Abstract - With the increasing demand of IoT and portable devices which are battery operated, low power designs are very essential. Comparator is the most fundamental component that performs comparison operation in circuits. In this project an efficient 2-bit magnitude comparator circuit design is proposed. This technique reduces power consumption, propagation delay, and area of digital circuits while maintaining low complexity of logic design when comparing with the traditional circuit. The performance analysis of proposed 2 bit magnitude comparator is compared with the existing technologies. The simulations are carried out in Tanner EDA tool.

Fig 1 depicts a 2 bit magnitude comparator with inputs A1, A0, B1, B0 and outputs A<B, A=B and A>B.

1.INTRODUCTION

Nowadays the semiconductor industry has been exhibiting a rapid pace of performance improvements in its products by shrinking the device geometries. The electronic devices of such products need to dissipate low power in order to conserve battery life and meet packaging reliability constraints. Consequently power consumption is a dramatic problem for all integrated circuits designed today. In the last decade, IoT devices, portable electronics such as smart phones, tablets and sensors has increased dramatically. Most of these devices are battery operated and thus power consumption has become a critical design constraint. Therefore, researchers set out to discover new methods for designing low-power electronics. Comparator is an integral part of many of the electronic circuits. When some emerging technologies are combined in the circuit, the performance and efficiency can be enhanced.

A 2 bit magnitude comparator is a hardware electronic device that takes two numbers as input in binary form and determines whether one number is greater than, less than or equal to the other number by utilizing various logic gates.

Fig -2: Gate implementation of 2 bit magnitude comparator

The gate implementation of 2 bit magnitude comparator using three NAND gates, 2 EX-NOR gates, one AND gate and one NOR gate is shown in fig 2.

The outcome of 2-Bit magnitude comparator is shown in Table 1 for different combinations of input vectors.

According to different condition of inputs, appropriate outputs are generated.

2. CONVENTIONAL DESIGN

Most of the digital circuits are generally designed using various logic styles. Nowadays, hybrid designing is a new methodology followed by circuit designers for efficient performance of the circuit. It is a new approach of designing in which two or more trending low power techniques are combined to form an effective circuit exhibiting low power, area and delay.

2.1 PTL-CMOS HYBRID DESIGN

Since hybrid designing is a trending method in low power designing, PTL-CMOS hybrid 2 bit magnitude comparator is one of the existing design. The 2-bit Magnitude Comparator has a binate composition of input variables. When it is implemented by using a synthesis of Pass Transistor Logic and CMOS logic styles, very low trends in power consumption, delay, power delay product and area in terms of transistor count were obtained. Fig 3 depicts the 2 bit magnitude comparator circuit using PTL-CMOS hybrid technology. The circuit is comprised of two PTL XOR gates, six CMOS NAND gates and a CMOS AND gate. This design of magnitude comparator has achieved 50-90% reduction in power consumption. Even though the existing design is

hybrid, an upswing in power consumption, delay and PDP is observed and curtailment of the design parameters can be prevailed using other hybrid designs.

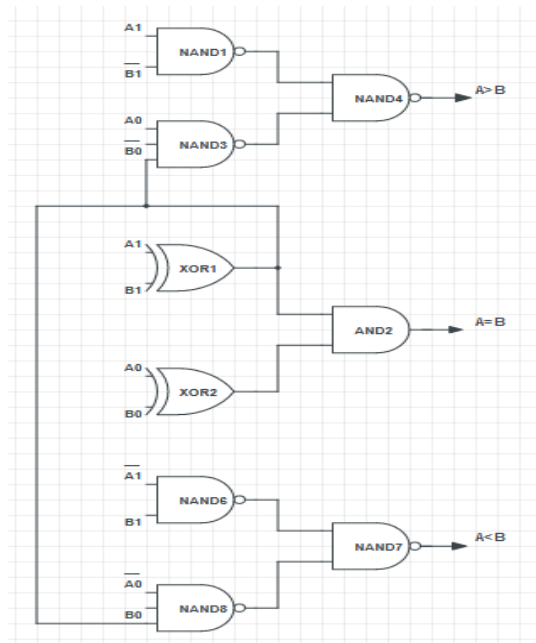

Fig -3 PTL-CMOS hybrid circuit

3. SELF CONTROLLABLE VOLTAGE LEVEL

Self-Controllable Voltage Level (SVL) circuit is a low power technique which can significantly decrease power consumption while maintaining high-speed performance of the circuit. It comprises of an upper SVL circuit and a lower SVL circuit. The SVL circuit is portrayed in fig 4.

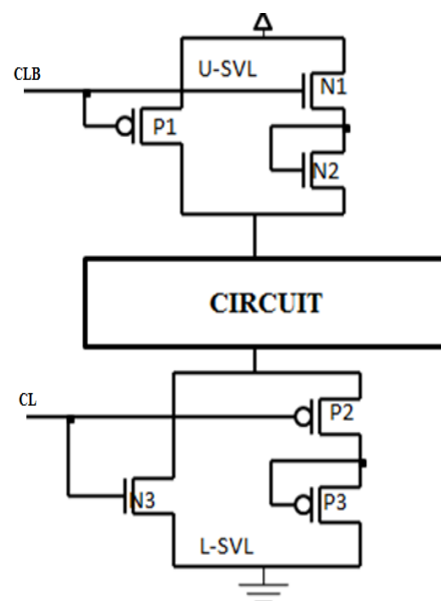

Fig -4 Self Controllable Voltage Level (SVL) circuit

The U-SVL technique is a combination of a PMOS and two NMOS transistors that are linked in parallel. Here an input clock pulse is fed to drive PMOS of U-SVL circuit and the remaining all NMOS are connected to drain terminal.

For small Power consumption applications, U-SVL technique is most accountable. The L-SVL system is an incarnation of an NMOS and two PMOS that are linked in parallel. Consequently an input clock pulse is applied to the NMOS of L-SVL circuit and the remaining all PMOS are connected to the ground. The ground terminal is allied to the L-SVL circuit.

When clock is low in U-SVL, PMOS would turn ON and maximum amount of V_{DD} is passed to load circuit. This is referred to as the active mode. In standby mode, clock is made high so that PMOS is turned OFF and NMOS is turned ON. Thus V_{DD} to the load is reduced and threshold voltage of NMOS in the load circuit is magnified. This in turn minimize subthreshold conduction and leakage current. By the utilization of this technique, sufficient amount of leakage current, PDP and average power can be considerably diminished.

4. PROPOSED DESIGNS

4.1 GDI-CMOS HYBRID DESIGN

The 2 bit magnitude comparator designed using hybrid combination of GDI and CMOS logic style is shown in Fig 5. The design comprises of different logic gates designed with GDI and CMOS. The proposed design shows good performance and power reduction with the incorporation of low power technique called SVL in the design.

Fig -5 GDI-CMOS circuit

4.2 PTL-GDI 1 HYBRID DESIGN

The 2 bit magnitude comparator designed with a combination of PTL and GDI logic styles to form a hybrid design is shown in Fig 6. The designed circuit comprises of logic gates using PTL and GDI styles. The low power technique known as SVL is added along with the circuit to reduce the power consumption and delay to provide better performance.

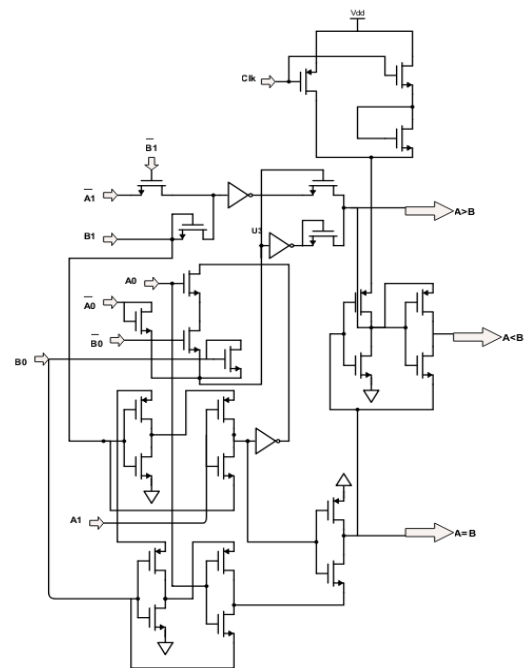

Fig -6 PTL-GDI 1 circuit

4.3 PTL-GDI 2 HYBRID DESIGN

Hybrid 2 bit magnitude comparator designed using PTL and GDI logic style is shown in Fig 7. The design along with low power technique, SVL provides better performance by reducing power and delay.

Fig -7 PTL-GDI 2 circuit

4.4 PTL-GDI 3 HYBRID DESIGN

Circuit design styles in VLSI, PTL and GDI are combined to give a hybrid 2 bit magnitude comparator which enables better power reduction and less delay with SVL in the design. This in turn shows good performance. The circuit is depicted in Fig 8.

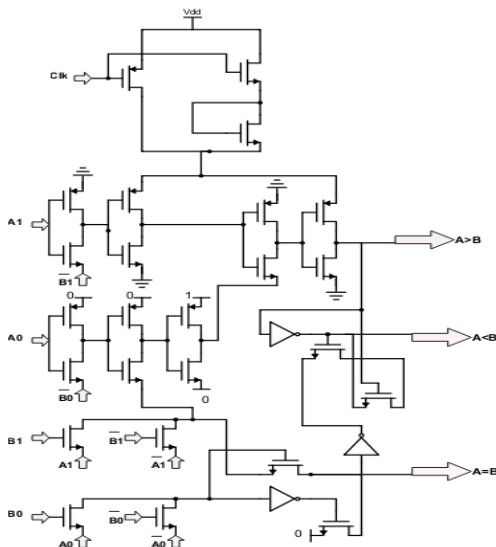

Fig -8 PTL-GDI 3 circuit

4.5 PTL-GDI 4 HYBRID DESIGN

PTL and GDI combination gives another hybrid 2 bit magnitude comparator which is shown in Fig 9. SVL technique is incorporated in the circuit design so as to reduce the power and delay to provide good performance.

Fig -9 PTL-GDI 4 circuit

5. RESULTS AND ANALYSIS

5.1 WAVEFORM

Figure 10 depicts the obtained waveform of 2 bit magnitude comparator.

Fig -10 Waveform of 2 bit magnitude comparator

5.2 COMPARISON OF POWER, DELAY AND POWER DELAY PRODUCT

As far as electronic circuits are concerned, power consumption is a major bottleneck of system performance. The main source is the dynamic power consumption. As long as there are a number of dynamic power reduction techniques, the system performance can also be enhanced by

reducing the leakage power consumption. Along with that, the most effective leakage power reduction method i.e. SVL can be incorporated with the design. When comparing the performance and power with different hybrid designs, the design incorporating SVL shows better reduction in the total power.

Table -2: Comparison of power, delay and PDP

Magnitude Comparator	Power	Power with SVL	Delay	PDP (Wps)
GDI-CMOS	37.14e-004	14.22e-004	123.7 p	0.1759
PTL-GDI 1	6.517e-004	4.543e-004	20.14 n	9.149
PTL-GDI 2	17.82e-004	11.13e-004	25.93 p	0.0288
PTL-GDI 3	7.679e-004	5.441e-004	25.93 p	0.014
PTL-GDI 4	5.802e-004	2.61e-004	10.47 n	2.7326

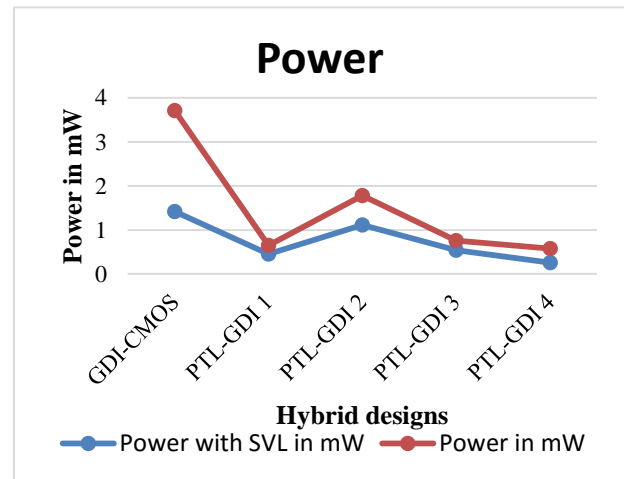

Chart -1: Power Comparison

Chart 1 is the portrayal power consumption of various proposed hybrid designs of 2 bit magnitude comparator. It is very obvious that when the designed 2 bit hybrid magnitude comparator circuits are incorporated with the power reduction technique SVL, a tremendous reduction in power dissipation is observed. With precise evaluation the proposed PTL-GDI 4 design dissipates comparatively much less power than the conventional circuits.

The proposed designs when consolidated with SVL, enhances the performance by lowering the propagation delay. The same is outlined as a graph in Chart 2 which illustrates that the proposed PTL-GDI designs exhibit better performance in terms of delay.

Chart -2: Delay Comparison

Chart-3 Power Delay Report

The Chart-3 represents the power delay product of various proposed hybrid designs. From the surveillance, PTL-GDI designs provide better performance in terms of PDP.

6. CONCLUSION

A 2-bit hybrid magnitude comparator circuit is designed using different logic styles such as GDI, PTL, CMOS and SVL. Simulations are carried out and the power analysis of the circuits have been performed. From the observations it is evident that PTL-GDI 4 is the efficient design with minimum power consumption. Thus by combining the existing technologies an efficient hybrid circuit of a 2-bit magnitude comparator is designed. It ensures low power consumption, propagation delay, and area of digital circuits while maintaining low complexity of design when compared with the existing comparator circuit using traditional logic styles.

ACKNOWLEDGEMENT

We would like to acknowledge the support of Department of Electronics and Communication and our HoD who provided us an opportunity and motivation to gain knowledge through this type of work. We are also thankful to Ahalia School Of Engineering And Technology, Palakkad for providing facility for preparing this paper.

ABSTRACT

This study deals with the subgrade soil stabilization in the Ambad – Chirakkal Farm Road in Palakkad district of Kerala state. Silico-manganese dust is used as the stabilizing material. Silico Manganese Dust is an industrial by-product obtained from the arc-furnace while extracting manganese from its ore. In this study, the percentage of silico manganese dust added is 5%, 10%, 15% and 20% by weight of soil for finding the optimum percentage. California bearing ratio (CBR) test and Unconfined Compression Test were performed to determine the strength properties of the Soil– silico manganese dust mixtures. Higher CBR values of soil- silico manganese dust mix extent their potential for use as a Subgrade for flexible pavement. The optimum CBR and UCC value were obtained at 10% addition of silico manganese dust.

Keywords : CBR, UCC, Soil- Silico Manganese dust mix, MDD and OMC

1 INTRODUCTION

Performance of Flexible Pavement depends on the functions of the component layers especially Subgrade. Subgrade is compacted layer of soil provide the lateral support to the pavement. Construction over soft subgrade affects the performance of pavement and results in shorter life of pavement. The typical approach of stabilization of soft subgrade is to remove the soft soil, and replace it with soil of high strength. The high cost of replacement of poor soil has caused highway agencies to assess alternative methods to construct the highway over soft subgrade. One approach is to improve the properties of soil is with addition of the waste materials. Soil stabilization is one of the most suitable alternatives which are widely used in pavement construction. Soil stabilization technique used to improve the engineering properties of soil such as strength and stability.

Traditional additives like cement, lime, fly ash can improve soil properties by themselves [12]. Non-traditional additives like rice husk ash, crumb rubber, marble dust, blast furnace slag can also improve soil properties but are less efficient[1][2][10][13][9]. But combining two or more non-traditional additive can improve their effectiveness[11][1]. RHA imparted strength combining marble dust increased the durability of soil specimen. Non-traditional additives should be used as soil stabilizer as they provide an economical alternative and also help in waste disposal[1][8][14]. In this study silico manganese dust is used as the stabilizing material.

2 OBJECTIVES OF THE STUDY

- To improve the CBR and UCC value of the subgrade soil
- To determine the MDD and OMC of the soil- silico manganese dust mix
- To design the flexible pavement as per IRC: 37 – 2012 guidelines.
- To perform the economic analysis of designed pavement with and without stabilization of subgrade soil.

3 MATERIALS USED

3.1 SUBGRADE SOIL

The soil was collected from Ambad – Chirakkal Farm Road in Palakkad district of Kerala state where it is proposed to construct a new flexible pavement. Experiments are conducted as per IS procedure to determine the properties of the subgrade soil and the test results are tabulated as follows:

Table 3.1 : Properties of soil used

PROPERTIES		RESULTS
SPECIFIC GRAVITY		2.49
SOIL CLASSIFICATION		Clayey Sand Soil
LIGHT COMPACTION	Optimum Moisture Content (OMC)	14.23 %
	Maximum Dry Density (MDD)	1.86 g/cc
HEAVY COMPACTION	Optimum Moisture Content (OMC)	6.345 %
	Maximum Dry Density (MDD)	2.38 g/cc
CALIFORNIA BEARING RATIO (CBR)		5.81%.
UNCONFINED COMPRESSION (UCC)		14.72 KN/m ²

3.2 SILICO MANGANESE DUST

Silico Manganese Dust is an industrial by-product obtained from the arc-furnace while extracting manganese from its ore. Silico Manganese Dust waste is obtained from the production of ultra low carbon silico manganese. It is a very fine pozzolonic material produced during the manufacture of manganese by electric arc furnace. The manganese dust is formed when MnO₂ gas produced in the furnace mixes with oxygen, oxidizes to MnO₂. It condenses and forms manganese which is the major part of the smoke. These dusty smokes are collected in a bag. This industrial waste can be used to stabilize the soil.

Fig. 3.1 Silico - Manganese dust

Table 3.2: Chemical composition of Silico-Manganese dust

CHEMICALS COMPOSITION	SILICO-MANGANESE DUST
Magnesia	1484 ppm
Iron	4963 ppm
SiO ₂	92670.4 ppm
Lime	134896.7 ppm

4 PROPORTIONING OF SOIL AND SILICO-MANGANESE DUST

In this study, the percentage of silico manganese dust added is 5%, 10%, 15% and 20% by weight of soil for finding the optimum percentage. The Soil - Silico-Manganese Dust mix are proportioned and designated as S1, S2, S3, S4, and S5 is shown in the table below.

Table 4.1: Proportioning of Silico manganese dust

SL No.	PROPORTIONS	DESIGNATION
1	SOIL + 0 % SILICO-MANGANESE DUST	S1
2	SOIL + 5 % SILICO-MANGANESE DUST	S2
3	SOIL + 10 % SILICO-MANGANESE DUST	S3
4	SOIL + 15 % SILICO-MANGANESE DUST	S4
5	SOIL + 20 % SILICO-MANGANESE DUST	S5

5 GEOTECHNICAL CHARACTERISATION

Detailed laboratory experiments were carried out to study geotechnical characteristics of Silico-Manganese dust and soil mix as per IS, which include: (a) Modified proctor compaction test [as per IS 2720 (part 8)] (b) Unconfined compressive strength test [as per IS 2720 (part 10)] and (c) California bearing ratio test [as per IS 2720 (part 16)]. The test was conducted and the results were obtained as tabulated in table 5.1. The detailed discussion on test results were done in the following sections.

Table 5.1 : Summary of test results

DESIGNATION	OMC (%)	MDD (gm/cc)	UCC (kPa)	CBR Value (%)
S1	6.345	2.38	14.66	5.81
S2	7.61	2.43	19.89	7.16
S3	8.482	2.52	27.48	8.86
S4	8.696	2.46	24.38	7.67
S5	9.167	2.35	16.91	5.44

5.1 MODIFIED PROCTOR TEST

The variations of MDD and OMC with addition of Silico-Manganese dust are shown in the figure. It is observed that the MDD value at 0% is 2.38 gm/cc and it increases upto 10% addition of Silico-Manganese dust with a MDD value of 2.52 gm/cc, then further increases in Silico-Manganese dust content causes decrease in MDD value of the soil. That is, at 15% addition of Silico-Manganese dust, the MDD value decreases to 2.46 gm/cc. The addition of dust causes densification initially, but later causes decrease in the density. The optimum value of MDD is 2.52 gm/cc at OMC of 8.482% by weight of soil with optimum Silico-Manganese dust content of 10% respectively.

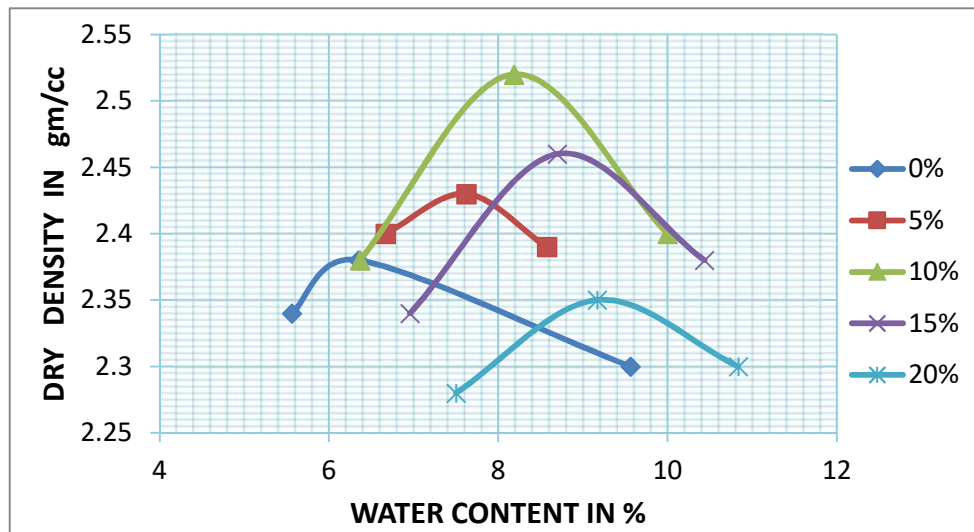

Figure. 5.2: Dry Density v/s Water Content with addition of Silico-Manganese Dust

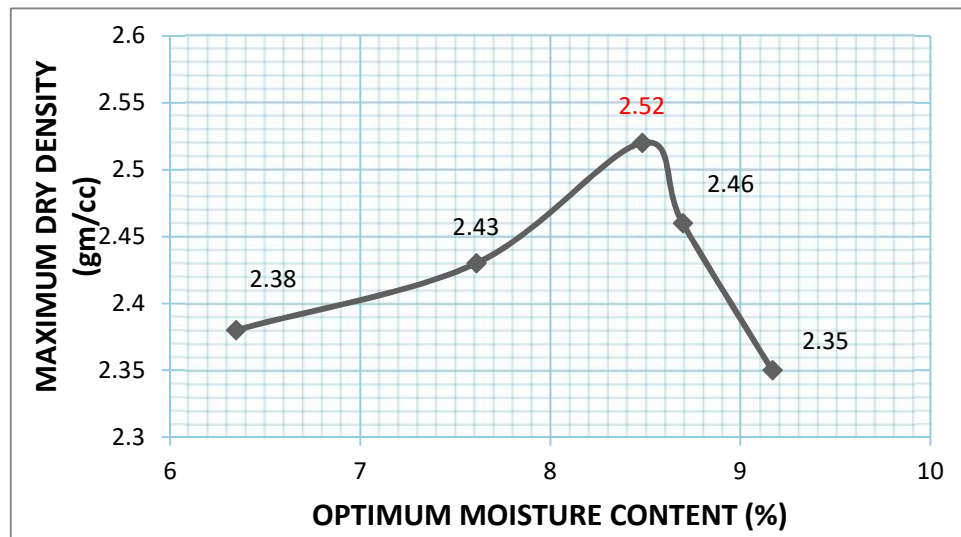

Figure 5.3 : Variation of OMC and MDD with addition of Silico-Manganese Dust

5.2 UNCONFINED COMPRESSION TEST

The variations of unconfined compressive strength with addition of Silico-Manganese dust are shown in the figure. It is observed that the UCC value at 0% is 14.66 kPa and it increases upto 10% addition of Silico-Manganese dust with a UCC value of 27.38 kPa, then further increases in Silico-Manganese dust content causes decrease in UCC value of the soil. That is, at 15% addition of Silico-Manganese dust, the UCC

value decreases to 24.38 kPa. The optimum UCC value is 27.38 kPa with optimum Silico-Manganese dust content of 10% respectively. The addition of dust causes densification initially, but later causes decrease in the density and thus the UCC value.

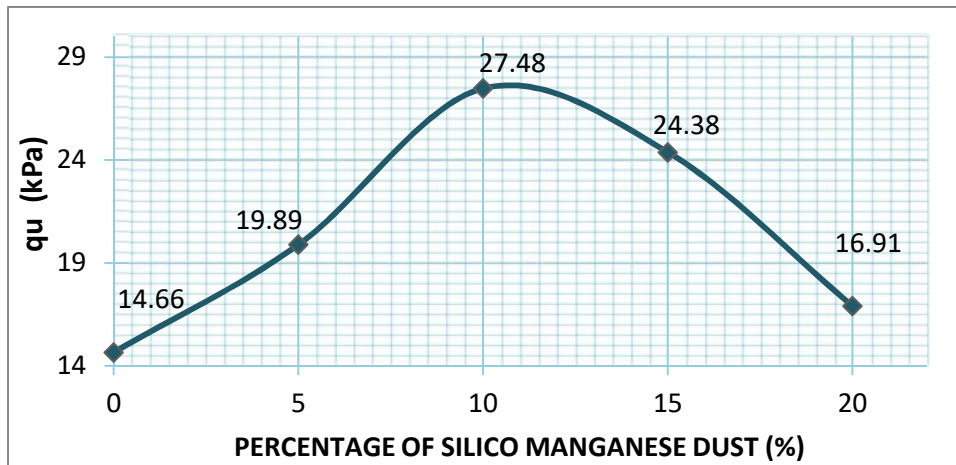

Figure. 5.4: Variation of UCS with addition of Silico-Manganese Dust

5.3 CALIFORNIA BEARING RATIO

The variations of CBR value with addition of Silico-Manganese dust are shown in the figure. It is observed that the CBR value at 0% is 5.81% and it increases upto 10% addition of Silico-Manganese dust with a CBR value of 8.86%, then a further increase in Silico-Manganese dust content causes decrease in CBR value of the soil. That is, at 15% addition of Silico-Manganese dust, the CBR value decreases to 7.67%. The optimum CBR value is 8.86% with optimum Silico-Manganese dust content of 10% respectively.

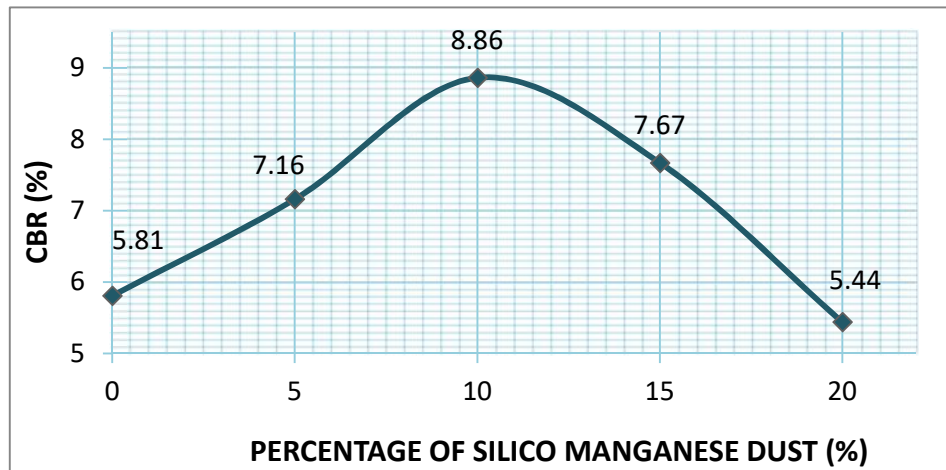

Figure. 5.5: Variation of CBR Value with addition of Silico-Manganese Dust

6 DESIGN OF FLEXIBLE PAVEMENT

The thickness of pavements and thickness for each layer is designed as per “IRC : 37 – 2012. Taking, design traffic $P = 52$ vehicles per day, Lane distribution factor $D = 0.75$, Annual growth rate $r = 7.5\% = 0.075$, Design life $n = 20$ years, Vehicle Damage Factor $F = 4.5$.

6.1 Pavement Thickness Without Stabilization of Subgrade Soil

Total Thickness of the Pavement = 537.16 mm

Thickness of GSB Layer = 228.58 mm

Thickness of G.Base Layer = 234.7mm

Thickness of DBM Layer = 51.94 mm

Thickness of BC Layer = 21.94 mm

6.2 Pavement Thickness With Stabilization of Subgrade Soil

Total Thickness of the Pavement = 452.76 mm

Thickness of GSB Layer = 150 mm

Thickness of G.Base Layer = 231.46mm

Thickness of DBM Layer = 50 mm

Thickness of BC Layer = 21.29 mm

$$\begin{aligned} \text{Percentage Reduction in pavement thickness} &= \frac{51.94 - 452.76}{51.94} \times 100 \\ &= 15.71\% \end{aligned}$$

Figure 6.1 : Cross section of the designed pavement

7 COST ANALYSIS FOR PAVEMENT WITH AND WITHOUT STABILIZATION

Total cost for single lane road of 1274m long without stabilization = Rs. 11142069.92

Total cost for single lane road of 1274m long with stabilization = Rs.9545371.835

Total cost reduced = Rs.11142069.92 - Rs.9545371.835

= Rs. 1596698.085

Percentage Reduced = (Rs.1596698.085 / Rs. 11142069.92) x 100

= 14.33%

8 CONCLUSIONS

The engineering properties of the subgrade soil is also determined as per IS procedures. It is found that the CBR value of the soil is very low and thus the soil property needs to be improved by stabilization. The silico-manganese dust, a industrial waste is used as the stabilizer. After conducting several tests like Modified Proctor test CBR test, and UCC test by addition of silico-manganese dust by 5%, 10%, 15% and 20% by weight of soil and the following conclusions were made:

1. The value of OMC is 8.482% by weight of the Soil and Silico-Manganese Dust and the value of MDD is 2.52gm/cc with Optimum Silico-Manganese Dust Content of 10% by weight of soil.

2. From the results obtained from the test, it is found that the Unconfined Compressive Strength of the soil increases upto 10% of Silico-Manganese Dust and reduces with further addition of it. The highest Unconfined Compressive Strength of the soil obtained is 27.48 kPa.
3. From the results obtained from the test, it is found that the CBR value of the soil increases upto 10% of Silico-Manganese Dust and reduces with further addition of it. Thus the CBR value of the stabilized soil is 8.86%.
4. By stabilization of the subgrade soil the thickness of the pavement is reduced by 15.71% and thus, the cost is reduced by 14.33%.

9 FUTURE SCOPE

In soil stabilization using Silico-Manganese Dust on the variation CBR value and UCC value are studied. Furthermore researches can be done on effect of Silico-Manganese Dust on Atterbergs indices and limits, free swell index, direct shear test, permeability test, etc.

Editorial

Dr. P.R. Sreemahadevan Pillai

Director,

Ahalia Group Academic Institutions in India.

Two centuries back, globally there were only around 30 scientific and medical journals, all printed. By 1900, it grew to over 700 and now nearly 40000 printed journals, publishing almost 3 million articles per annum. Online journals are yet to be counted. In the years to come, online journals will be more popular, going by the current trends. The most popular journals 'NATURE' and 'SCIENCE', with impact factor over 40, begun publishing in the 19th century, are still available in print mode only. Journals permit us to explore and follow research, for generating the required results. It is of essential help for collecting information and analyzing data. For comprehensive research, academic or scientific journals are a sine qua non.

The myriad advantages of journals are worth mentioning. They provide credible and authentic information. Availability of contrasting opinions will help us to search further. Conclusions can be drawn based on the truths presented. Journals offer varied research options for better results. Case studies available in journals help us to make better research hypotheses. The wealth of knowledge available in journals enrich and update our knowledge base. Narrowing the research to focused angles is facilitated by the variety of options available in journals. The freedom of access to knowledge in abundance is an added advantage. Journals provide a broadened perspective on topics and thus different views. The availability of knowledge in myriad forms is an added advantage. For the past two centuries, scientific journals have taken us to a new vista and promoted a scientific temper globally.

The Ahalia International Journal of Advanced Science and Technology is initiated with all the above purposes. Initially it is proposed to be published as an online journal and later as print journal also. This is a peer reviewed journal. The listing and indexing procedures will be done in due course. We request the cooperation of the academic and scientific community across the globe to carry on with this venture. We are presenting before the learned readers, the first ever edition of this journal.

COVID-19 has forced the teaching community to switch to online classes in a short span of time. There are several challenges that a teacher faces when switching from traditional in-person classes to online classes. This paper presents the results of a survey on online classes that was conducted amongst the students, faculty and parents of Ahalia School of Engineering and Technology, Palakkad, Kerala, India. While the benefits of online classes are seen, majority of the participants of the survey prefer traditional offline classes. The paper also provides some specific pointers and suggestions for teachers to consider when transitioning from offline (or in-person) classes to online classes.

Keywords: online teaching, teaching techniques, pedagogy

1. Introduction

The only thing constant in life is change. In 2020, change was not something the world was prepared for. With the advent of the COVID-19, government bodies, international organizations, large and small business, families and individuals were forced to rethink their priorities and how they led their daily lives. In addition to the various sectors of the economy such as the healthcare, banking, transportation and tourism, the academic environment too was hit hard with the onset of the COVID-19 and the subsequent lockdowns [1] [2]. This is true in India as well as abroad. Some of the prominent matters that affected (and continue to affect) Universities, colleges, schools and other educational institutions include: loss of instructional time, mobility of students (particularly international students), digital learning and IT infrastructure, health and well-being of the students and staff members, examinations and re-opening of institutions.

The primary stakeholders – students, faculty members and parents – have been severely affected during this ongoing crisis. For students, the transition has meant listening to their teachers via an online medium in the comfort of their homes. The travel time back and forth from the institution is

eliminated, but so have their chances of meeting their classmates on a regular basis. The students also have to adapt to a new style of learning, where classes, discussions, tutorials, clearing doubts all happen online. As students, regardless of their background, community, economic and social status, spend more time at home their physical and mental health also needs to be given a priority. Parents too had to make significant changes in their daily routine to accommodate the fact that all their child's learning is now happening at home. The adverse consequences of school closures have also been identified by UNESCO [3].

The extended lockdown periods have forced many governments, small and large businesses to make changes in their daily operations; so did the teaching community. This fact is sometimes forgotten and under-appreciated. In India and Kerala in particular, when the lockdown was announced on March 2020 unexpectedly, all teachers had to immediately shift their classes to an online manner. For teachers in the higher education sector, this was quite a challenge as the lockdown was announced in the middle of the semester. While shifting classes online might sound easy, practically there are several challenges that need to be overcome by the teachers if online classes need to be effective. Some of these include: ensuring a reliable IT infrastructure at home, adequate knowledge and skills to use the relevant computer hardware and software and most importantly, modifying teaching styles to match the new learning styles of the students. At the heart of the problem, teachers must understand that by moving away from in-person classes and discussions, if not managed properly, the interactions between a student and a teacher will greatly reduce. To be effective, a teacher must carefully plan and implement an appropriate teaching-learning pedagogy [1] [4] [5] [6].

The goal of this article is to outline some important points and suggestions for teachers to consider when transitioning from in-person classes to online classes. In Section 2 of this paper, the results of a survey conducted amongst the stakeholders of Ahalia School of Engineering and Technology, Palakkad, Kerala, India is presented and discussed. In Section 3, a few suggestions to the faculty members to improve their online teaching approaches are mentioned. The conclusion of this work is summarized in Section 4.

2. Survey and Discussion on Online Classes

Ahalia School of Engineering and Technology (ASET) is located in Palakkad, Kerala, India. It is affiliated to the A. P. J. Abdul Kalam Technological University, Kerala and is approved by the All India Council for Technical Education (AICTE). Recently an anonymous survey was conducted amongst the students and their parents and the faculty members of the institution to review the conduct of online classes and its effectiveness. The results of this survey are presented in this section.

2.1 Response from Students

183 students, from all the five branches of engineering (Civil, Computer Science, Electronics and Communication, Electrical and Electronics and Mechanical) participated in the survey. The percentage of students from the various years of study is shown in Figure 1. Almost all the students reside in the Palakkad district of Kerala, in the same district where the Institution is located. The results of the survey are presented below.

- i. When asked whether the students have a reliable internet connection to attend to online classes, 70.5% of the students indicated that they have this facility.
- ii. Regarding the effectiveness of the online classes, only 16.4% of the students felt that the learning experience was better than offline (or in-person) classes.
- iii. The biggest advantage of online classes, when compared to offline (or in-person) classes, indicated by students (44.8%) is the ease of studying at home. The next major advantage, indicated by 37.7% of the students, is time savings. The other advantages mentioned by students include better explanation and understanding of subject material, avoiding travelling and the ability to revisit lectures via class recordings.
- iv. The biggest disadvantage of online classes, when compared to offline (or in-person) classes, indicated by students (59.6%) is not able to understand the subject properly. The next two disadvantages were missing the classroom environment and not meeting friends in the Institution, indicated by 19.7% and 12.6% of the students respectively. Other points mentioned were internet and related technical issues, increased strain due to continuously using a mobile phone or laptop, inability to concentrate or focus for the duration of the online classes, health concerns, lack of interpersonal relationships and interactions during classes.
- v. When asked about the type of subjects that they preferred to be taught online, 90.2% of the students preferred theoretical subjects to be taught online. For analytical and problem-based or numerical-based subjects, students preferred traditional offline (or in-person) classes.
- vi. When asked about the degree of interaction during online classes, when compared to offline (or in-person) classes, only 15.3% of the students found the classes to be very interactive. 45.4% of the students felt it ok/average while 39.3% of the students found the online classes not interactive.
- vii. Our Institution is using the Google for Education package and hence majority of the teaching-learning happens on the Google platform. Particularly, Google Meet and Google Classroom are used extensively. When asked about whether using Google Classroom was effective, 32.2% of the students indicated that it was very effective and 52.5% of the students found its use ok/average. The rest of the students (15.3%) indicated that it was not effective.
- viii. For circulating notes and study material, 74.3% of the students preferred Google Classroom and 20.2% of the students preferred WhatsApp. The other preferences indicated by the students include Telegram, both Google Classroom and WhatsApp and hardcopy of the notes.

- ix. Since the University to which our Institution is affiliated is conducting offline (or in-person) examinations, students were asked if they felt confident of passing the University examinations after the conduct of online classes. 66.7% of the students indicated that they are not confident of passing. This reinforces the need for offline (or in-person) classes before the University examinations and justifies the insistence of the University for Contact Classes (following COVID-19 norms) for all the batches prior to the examinations.

To summarize, though students in the Institution prefer online classes because of the convenience it provides and their benefits for certain types of subjects, in general offline (or in-person) classes are greatly preferred. This is particularly true from the point-of-view of University examinations and the fact that reliable network connection is not available to all students. Moreover, even though resources like the Google platform is used and is beneficial, the quality of the online classes need to be improved particularly when considering the level of interaction between faculty and students.

2.2 Response from Faculty

Twenty nine faculty members from various departments participated in the survey. The major results of the survey are presented below:

- i. When asked about their familiarity with conducting online classes, delivering talks or work shops or webinars via the online medium prior to the lockdowns, majority of the faculty members (55.2%) indicated that they were not involved in such activities.
- ii. The faculty members were also asked about how easy it was to transition from offline (or in-person) classes to online classes. Majority of them (86.2%) indicated the transition was ok/average and 10.3% of the faculty found it very difficult.
- iii. Regarding the difficulties that faculty members faced while handling online classes, majority of them (62.1%) indicated the lack of interaction with students and the lower satisfaction after covering a particular topic when compared to offline classes as the major factors. 27.6% indicated the need to modify their teaching style as another challenge they faced. 17.2% indicated the lack of reliable IT infrastructure at home as a difficulty. Only 3.4% indicated the lack of adequate knowledge and skills to use computer hardware and software as an area of concern.
- iv. In our Institution faculty members were involved in handling online classes for more than one semester. Based on this experience, they were asked whether they preferred online or offline classes for the upcoming semester. Majority of the faculty members (89.7%) indicated that they preferred offline classes.
- v. When asked whether the faculty made any changes to their notes, lecture material or related material for the purpose of online classes (when compared to the offline classes), 86.2% of the faculty indicated in the positive. 10.3% of them indicated that they had not made and changes and 3.4% indicated that they were teaching the subject for the first time.
- vi. Lastly, the faculty members were also asked if they had employed any new strategy (e.g. flipped classroom, pop-quizzes, etc.) when handling online classes. 65.5% indicated that they had while 34.5% indicated that they had not.
- vii. The faculty members were also asked to give their suggestions for improving the quality of online classes. The relevant suggestions are: improving connectivity and the need for a reliable network, the use of digital or interactive boards, ensuring participating and better communication with students during online classes.

To summarize, even though most of the faculty members are adept at using technologies and were

adaptive to the change from offline to online classes, majority of them prefer traditional offline (or in-person) classes. However, with the changing face of education and the well-documented reasons for digital or online education, it is very important that faculty members are equipped with the necessary techniques, skills and trainings to meet the changing needs and demands of the education system. In Section 3 of this paper, a few specific suggestions for faculty members are outlined.

2.3 Response from Parents

Nineteen parents participated in the survey. While this is not a large number to draw a reasonable conclusion, the results of the survey are listed below.

- i. When asked if they preferred their child to learn via online classes or offline (in-person) classes, majority (73.7%) indicated offline classes.
- ii. When asked whether the online classes conducted were effective for their ward, 52.6% indicated in the positive.
- iii. The parents were also asked if they faced any difficulty at home due to their ward's online classes. 68.4% indicated that they did not face any difficulty.

3. Discussion and Suggestions for Faculty

Based on the experiences from 2020 and looking ahead, digital teaching-learning and online education will play an important role in the academic environment. Many Universities have already permitted students to transfer credits earned from online courses such as SWAYAM [7] towards their degree. Faculty development programmes and teacher training and evaluation programs via the online medium has also seen a rise through platforms such as ATAL [8] and ARPIT [9].

While there is a great deal of focus on connectivity and related IT infrastructure, it is equally important to remember that learning outcomes are met only when a teacher uses appropriate strategies and pedagogies that is adaptive and matches the capacity of the students. As indicated earlier, there are many resources available to faculty members that cover the topic of teaching pedagogies and strategies, and this section presents a few specific suggestions for faculty members, particularly when dealing with online classes.

- With the advent of COVID-19, there is an increased use of software platforms such as MOODLE, Google Classroom, Microsoft Teams, WhatsApp etc., by the teachers to communicate with the students. This communication takes the form of providing study materials, conducting group discussions, conveying important announcements, etc. While the above mentioned tools serve as a good repository for study materials, it is especially important in the present situation, that the materials are published in an organized manner. This will help the students retrieve and easily access the materials posted. Some tips include using tags or topics to organize material into various categories, naming the files being uploaded appropriately and using proper titles for various posts.
- One of the main advantages of switching over to an online teaching-learning methodology is that teachers can easily share references and links of online materials such as articles and videos. In situations where difficult concepts are being taught, extremely good videos, already available on the internet, can supplement the teacher's classes. This is very useful from a student's perspective. Thus it is extremely important that a teacher knows how to include links of various online resources to software platforms such as Google Classroom.

- When shifting to online classes, an important resource is often the notes that a teacher provides. This is the primary resource for students, especially when access to textbooks and reference books from their homes is difficult. It is also hard and time consuming to verify whether the students are making class notes during online lectures. In addition to providing such study material, a faculty must also think about how to present the concepts in these study materials for a greater learning experience by the students. One example is including the learning objectives of the particular topic being covered in the notes at its beginning. Another example is including a summary or “do you know?” questions at the end of the notes. Another example is ensuring the ability to simultaneously draw diagrams and add annotations when explaining concepts given in the notes. These annotated notes can be shared with the students as well. The major benefits reported by students include: (i) it helps to quickly recollect the material during the time of revision, (ii) it gives a clear picture of what is going to be covered and (iii) it reduces the chances of skipping important points while learning.
- It is often stated that after approximately fifteen minutes, the attention span of an audience dwindles during a lecture or talk. Thus it is often encouraged to take a short break in some form (e.g. cracking a joke, an activity, etc.) during classes as it will recharge the audience. This concept is even more important when handling online classes on platforms such as Google Meet, Zoom, Cisco Webex or Microsoft Teams. It is also crucial to keep in mind that most students especially in the higher education, attend these classes on their mobile devices via their data connection. The situation is made more challenging as students often turn off their video to ensure adequate speeds and audio quality during the class. This often poses a difficult situation for the teachers as there is no visual feedback from the students, thereby making it hard to understand the involvement and attention of the students. One tip is for the teacher to engage in oral pop quizzes where the students are called out by name to answer questions in a random manner. This is one way of checking whether the students are alert and engaged in the online class. Another possible technique is to conduct written pop quizzes. For example, after fifteen or twenty minutes of class a multiple choice quiz (MCQ) on the material covered in the lecture can be conducted for another five or ten minutes. The MCQ can be conducted on a platform like Google Forms, where the students can immediately know the points scored, which questions they made a mistake, the correct answer to the questions and some feedback on the answers. The auto-grading facility is a great tool here, as the teachers can immediately know which questions posed a difficulty to the students. Thus the discussion thereafter can be focused on these questions. Some of the benefits reported by students include: (i) it serves as a reminder to listen to the class properly, (ii) it improves the confidence of the student in that topic, (iii) it helps to recollect material and (iv) it serves as a good revision on the topic discussed. Such quizzes have the added benefit of breaking the monotony of the online class, improve interaction with the students and they also provide an indirect way to measure their attendance in the class.

4. Conclusion

With the trend in education moving towards a greater appreciation for MOOCs, online certifications and online degrees, even with the release of the COVID-19 vaccine, the concept of online teaching and learning is here to stay for the foreseeable future. Thus it is up to the teacher to find creative ways of engaging the students. In future the effectiveness of a teacher will be partly measured by the expertise and experience in conducting online classes. This paper presents a survey on online classes that was conducted amongst the students, faculty and parents of Ahalia School of Engineering and Technology, Palakkad. The paper also provides some specific suggestions for faculty members to improve their on-

line classes. The points mentioned in this paper are not in any way exhaustive and are only ideas for teachers to consider while engaging online classes. In this context it is imperative to say that online teaching requires more effort from the teachers, if the classes are to be enjoyable and effective.

Role of Ahara according to Manasa Prakruti- A Conceptual Study

Dr. Durga E.

Associate Professor

Kayachikitsa Department

Ahalia Ayurveda Medical College, Palakkad, Kerala

Email: drdurgae@gmail.com

Abstract

Ayurvedic principles state a strong connection between food and the human mind. The mind is directly influenced by the quality, method of preparation, appearance, freshness and aroma of the food. Ayurveda advocates that the quality of food influences mental agility and vigour and even emotion. Ahara improve nutrition, immunity and health when used in proper time and in a suitable individual. The purpose of life is to achieve fourfold objectives, viz. virtuous acts (Dharma), acquisition of wealth (Artha), gratification of desire (Kama) and salvation (Moksha). These pursuits can be achieved through austerity (Tapa), studies (Adhyayana), celibacy (Brahmacarya), fasting (Upavasa) and religious vows (Vrata). Diseases are major impediments to these sacred duties and lone remedy is that of preventing the body from falling ill by achieving a state of positive health. Thus health (Arogya) stands at the very root of achieving the four pursuits of life. The very objective of Ayurveda is achieving healthy status of the body. Both Caraka and Susruta outline similar objectives. They are to maintain the health of the healthy and to cure the disease of the diseased. Caraka in different context states that the object of the science is the maintenance of the equilibrium of the tissue elements (Dhatu). Disequilibrium among tissue elements is postulated as disease and equilibrium as health.

Keywords: Ahara, Ayurveda, Satvika, Rajasa, Thamasa

1. Introduction

Health is a state of wellbeing at all the four planes of life, viz. Soma, senses, psyche and the spirit. Balanced state of the constituents of body (Dosha, Dhatu, Mala and Agni) and satisfaction or pleasure of senses, mind and the soul constitute health.

Upastambha

According to Ayurveda the Upastambha (supporting pillar triads) required for the maintenance of human body are Ahara, Brahmacharya and Nidra. The individual is no longer healthy unless he receives a healthy food. Hence a proper selection of food is also inevitable to drive out the susceptibility of disease. In modern science they only consider the quantitative values in the body like electrolyte, fat, proteins, iron etc. in percentage concerned with the maintenance of health. As a feedback, only they advise various restriction in food intake. Relevant theory regarding this is a famous one that 'A healthy mind dwells in a healthy body'. [1] Meanwhile Ayurvedic treatises provide a vast collection of information regarding the action of food influencing mind. They have explored deeply along the various action by studying Rasa, Guna, Veerya, Vipaka, Prabhava etc. The relationship between

food and mood is bidirectional. Food affects the person's mood through physiological mechanisms and the person's mood plays a strong role in determining the choice of food. The food we eat has a significant influence on our mind. The nature of our mind and feelings depends on the food we have eaten. And conversely, the state of our mind, emotion, intellect and senses and our overall state of contentment-all these, in turn, affect the digestion, absorption and elimination of the food we have eaten.

In the present era the whole behavior and food habits have been changed. Most people now a day used to take certain trend of food habits like fast food, preserved foods etc. They are not ready to discriminate what is good and what is bad for health. The foods, which is easy to cook, and good in external appearance, good in flavor and attractive, preference goes in this way. The prior prepared and preserved foods, food that is readily ingestible, chilled beverages, etc. are only taken in to account. Even water itself is used in packed form as a status symbol.

According to naturopathy man is considered basically as a fruitarian. The scientific analysis of the anatomy and of physiology of human digestive system by the modern science also approves the same. The holy bible says the great grandparents of the mankind were provided an Eden garden, which was full of fruits. Even though our Acharyas have given enough references regarding vegetarian and non-vegetarian foods, in very few instances they advise non-vegetarian foods for ingestion. But here in this context the food those exerts any influence on mind only comes under the purview. In fact, Ayurveda Considers the body including the faculties as well as mind sets substratum for every disease. There is close relation between psyche and soma and so the psychosomatic concept is much appreciated. The body humors in their normalcy perform much psychological function as well. In general practice people indulged in non-vegetarian food seems to be more aggressive emotional and sentimental in nature. This is not mere an assumption because medical experts can easily compare the relationship between food and behavior.

Chandogya Upanisad links the origin of mind with food and states that the tenuous (subtlest) portion of food becomes the mind, the basis of the so-called physical nature of mind.

Annamasitam tredha Vidheeyate tasya ya stavishto dhatu tat pureesham bhavati, somadhyamastanmamsam, Yo anishtastanmana

Annamayath hi Soumya manah. The testimony is further given by the incident of Svetaketu who did not eat food for fifteen days and lost all his memory. On eating food on 16th day, he could recall his knowledge. Implications of this concept are dealt elsewhere. Chandogyopanishad again emphasizes the relation between the food and mind. The mind is what we eat and a food that is pure results in a clean state of mind.

Ahara shudhou Satva Shuddhi, Satva Shudhou Dhruva Smriti

A clean mind has memory which transcends many births. This very verse probably is the basis for Gita's classification of food into Satvika (pure), Rajasika (pungent) and Tamasika (impure) varieties. In Bhagavad Geetha some references can be seen accessible to the same theory. From Satva results knowledge, from Rajas only greed and from Thamas delusion and ignorance itself.

Satvika food

Normally they like the foods that augment life energy, strength, health, happiness, joy and which are savory, nourishing and agreeable. In Ayurveda the fourfold type of food mentioned should possess the above qualities. For demonstration foods like milk ghee, fresh and sweet fruits can be included in this Class.

Rajasa food

Rajas itself is to be of the nature of passion the source of desire and attachment. It prompts the self by attachment of action.

The foods that are very pungent, sour, hot, saltiest, dry and burning are liked by Rajasa and it will be conducive to pain grief and disease. Generally, the food habits of population are going in such a way. Consequently, from the society itself a lot of live examples like evil acts, quarrels, and impatience suicidal and homicidal tendency etc. are vividly common.

Thamasa food

Thamas to be born of ignorance and deluding all embodied being it binds through inadvertence, laziness and inactivity. The food cooked three or more hours before i.e., which has become cold, worthless, from which the essence has gone, putrid, foul smelling, the balance after somebody's use, not good for intellect is liked by Thamasic people

As a part of time saving, the preservation and further use of cooked food is common now. Ayurveda also consider it as toxin and harmful for body and mind. Food preserved in fridges, cooked tin foods, Alcoholic and non-alcoholic beverages belong to this category. Uchchishta food clearly indicates the possibility of contamination of various Microbes.

Eight factors determining the utility of food

The eight factors which determine the utility of various types of food are: (i) *Prakrti* (nature of the food articles), (ii) *Karana* (method of their processing), (iii) *Samyoga* (combination), (iv) *Rasi* (quantity), (v) *Desa* (habitat), (vi) *Kala* (time) i.e., stage of the disease or the state of the individual), (vii) *Upayogasamstha* (rules governing the intake of food) and (viii) *Upayoktra* (wholesomeness to the individual who takes it).

Prakrti indicates the nature of the substance, i.e., inherent attributes (heaviness etc) of diets and drugs. Eg. Masha is heavy and Mudga is light and meat of Sukara (Boar) is heavy and that of Ena (Deer) is light

Karana means the processing of the inherent attributes of substances. Processing results in the transformation of the inherent attributes of substances. Transformation of the attributes is affected by dilution, application of heat, cleansing, churning, storing, flavoring, impregnation, preservation, container etc.

Samyoga is the combination of two or more substances. This results in the manifestation of specific attributes which cannot be manifested by individual substances e.g., combination of honey and ghee or honey, fish and milk

Rasi is the quantum of total (Sarvagraha) or individual (Parigraha) substances which determines the results of their administration in proper and improper dosage. The quantity of food taken in its entirety is 'Sarvagraha' and the quantity of each of its ingredients is 'Parigraha'. Quantity of all things involved is Sarvagraha and that of each and everything individually is Parigraha.

Desa relates to the habitat. It determines attributes due to procreation (growth) or movement of substances in a particular locality or their acclimatization to that region.

Kala stands for both the time in the form of day and night and the states of the individual, (viz. condition of Health and age). The latter is relevant to see disease whereas the former for the determination of the wholesomeness to different types of seasons.

Upayogasamstha stands for the dietetic rules. They are for the most part dependent on the symptoms of digestion.

Upayokta is he who takes food. He is, in the main, responsible for the wholesomeness by the habitual intake of things (Okasatmya).

Rules for taking food

Healthy individuals as well as the patients should observe the following, even while using such of the food articles as are most wholesome by nature. One should eat only that food in proper quantity which is hot, unctuous and not contradictory in potency and that too, after the digestion of the previous meal. Food should be taken in proper place equipped with all the accessories, without talking and laughing, with concentration of mind and paying due regard to oneself.

Right time for food intake

When faeces and urine are excreted, Hridaya becomes clear, Doshas traverse in their right pathways, belching becomes clear, hunger begins and Vata functions properly, digestive power increases, the body becomes light and capable of perceiving the senses; food is to be taken, as it is the right time scientifically recommended for food intake.

Manasa Prakruti

Prakruti in Ayurveda refers to an individual's inherent nature, the inborn tendencies which influence the consciousness and activity. Different meanings of Prakruti are nature, temperament, constitution, form, origin etc. Prakruti lakshana by Susrutacarya "Prakopo Va Anyadha Bhava Kshayo Va Nopajayate Prakrutinam Svabhavena Jayate Tu Gatayusha". The temperament of a man is never aggravated nor does it suffer any deterioration. A change or deterioration in any particular case should be regarded as the harbinger of death. Before undertaking the examination of the patient, it is necessary for the physician to have a thorough knowledge of the normalcy of the human being in all aspects. Nothing can be judged abnormal without knowing the normal. So it is essential that Prakruti Pariksha is to be done first and Vikriti Pariksha later. Acarya Charaka considers Prakruti as one of the Bhavas, while describing Dasa vidha Pareekshya Bhavas. According to Sankhya, there are three major attributes - Satva, Rajas and Tamas. All human beings have been basically grouped under these triads. Ayurveda considers Rajas and Tamas as Manodoshas capable of producing diseases and Satva as Manoguna. According to Ayurveda, the digestive enzymes and metabolic processes are likened to a

fire, called Kayagni in Sanskrit. How well we digest the food depends upon the strength of our Agni. We can say that the entire health and happiness of each individual depends on the strength and functioning of our Kayagni. In fact, one of the major limbs of Ayurveda is called Kayachikitsa, which is concerned with balancing Kayagni to bring health and happiness to the entire body-mind system. So both food and our moods have an effect on our digestion, and conversely the strength of our digestion has an effect on our moods.

Ayurveda is the science of life and life according to Ayurveda is the state of union of four components namely, the body (Sareera), the sensory and motor faculties (Indriyas), mind (Manas) and soul (Atma). Mind is considered as Ubhayendriya. It is located in the body itself and can be considered as the super faculty. According to Caraka, mental faculty is of three types-Satvika, Rajasa and Tamasa. The Satvika one is free from defects as it is endowed with auspiciousness. Rajasa type is defective because it promotes wrathful disposition. The Tamasa one is similarly defective because it suffers from ignorance. More over the word Satva is also used as a synonym of mind. Rajas is a factor of aggression (Rosha) and Tamas is a factor of confusion (Moha). Mind influenced fairly and constantly by the predominance of Rajas is called Rajasa satva and similarly influenced by Tamas is called Tamasa satva. Mind that is not affected by Rajas and Tamas is in its pure form and hence is called Suddha Satva.

Distinctive features of the different classes of mental temperaments:

Satvika features according to Ashtanga hridaya[2]

Saucam	Cleanliness
Astikyam	Belief in gods
Sukla dharma ruci	Inclination to follow the path of pure virtue

Satvika features according to Susruta Samhita[3]

Anrsamsyam	An absence of hostile propensities
Samvibhaga rucita	Judicious distribution
Titiksha	Forbearance
Satyam	Truthfulness
Dharmam	Religious acts
Astikyam	Belief in gods
Jnanam	Spiritual knowledge
Budhi	Intellect
Medha	Retentive faculty
Smrti	Memory
Dhrti	Comprehension
Anabhishangam	Doing good deeds irrespective of consequences

Rajasa features according to Ashtanga hridaya

Bahu bhashitvam	Talkativeness
Manam	Pride
Krudha	Anger
Dhambha	Vanity
Matsara	Jealousy

Rajasa features according to Susruta Samhita

Dukha bahulata	Feeling of much pain and misery
Atana seelata	Wandering tendency
Adrti	Non comprehension
Ahamkara	Ego
Anrtikatvam	Untruthfulness
Akarunyam	Unkindness
Dhambha	Vanity
Manam	Pride
Harsha	Joy
Kama	Lust
Krodha	Anger

Thamasa features according to Ashtanga hridaya

Bhayam	Fear
Ajnanam	Ignorance
Nidra	Excess sleep
Alasyam	Laziness
Vishadita	Grief

Rajasa features according to Susruta Samhita

Vishaditvam	Despair
Nastikyam	Not believing in existence of god
Adharma seelata	Irreligious stupefaction
Budhi nirodham	Perversion of intellect
Ajnanam	Ignorance
Durmedastvam	Silly thoughts
Akarma seelata	Lethargy in action
Nidralutvam	Sleepiness

The Satvika type of mental faculty is of seven types depending upon the disposition of Brahma, Rishi, Indra, Yama, Varuna, Kubera and Gandharva. Rajasa type having six types, namely Asura, Rakshasa, Pisacha, Sarpa, Preta and Sakuni. Tamasa type is of three types; Pasava, Matsya and Vanaspatya

Different types of Satvika individuals

1. Brahma (sharing the traits of Brahma)

Clean, love for truth, self restrained, power of discrimination, material and spiritual knowledge, freedom from passion, anger, greed, ego, ignorance, jealousy, dejection and intolerance and favourable disposition equally for all creatures.

2. Arsha (sharing the traits of Rsis)

Devotion to sacred rituals, study, sacred vows, oblations and celibacy, hospitable disposition, freedom from pride, ego, attachment, hatred, ignorance, greed and anger, intellectual excellence, power of understanding and retention.

3. Aindra

Lordship, authoritative speech, performance of sacred rituals, bravery, strength and splendour, far sightedness, devotion to virtuous acts, earning of wealth and proper satisfaction of desires

4. Yamya

Observance of the propriety of actions, initiation of actions in time, non violability, memory and lordship, freedom from attachment, envy, hatred and ignorance.

5 Varuna

Bravery, patience, purity, dislike for impurity, observance of religious rites, fondness for aquatic sports, exhibition of anger and pleasure in proper place.

6 Kaubera

Possession of honour, luxuries and attendants, constant liking for virtuous acts, wealth and satisfaction of desires, purity, liking for pleasures of recreation.

7 Gandharva

Fondness for dancing, singing, music and praise, expertness in poetry, stories, historical narrations and epics, constant fondness for scents, garlands, association of women and passion.

Of the seven types of Satvika mental faculties described above, Brahma is the purest.

Different types of Rajasa individuals

1. Asura

Bravery, cruelty, envy, lordship, movement in disguise, terrifying appearance, ruthlessness, indulgence in self prais

2 Rakshasa

Intolerance, constant anger, violence at weak points, gluttonous habit, fondness for non-vegetarian food, excessive sleep, cruelty.

3 Paisaca

Gluttonous habit, fondness for women, unclean habits, cowardice and terrifying disposition, resorting to abnormal diet and regimens.

4 Sarpa

Bravery when in wrathful disposition and cowardice when not in wrathful disposition, sharp reaction, taking food and resorting to other regimens with a fearful disposition.

5 Praita

Excessive desire for food, excessively painful disposition in character and past times, enviousness, actions without discrimination, excessive greediness.

6 Sakuna

Attachment with passion, excessive food and regimen, unsteadiness, ruthlessness and unacquisitiveness.

Different types of Thamasika individuals

The Thamasika type of mental faculty represents ignorant disposition and is of three types.

1. Pasava

Forbidding disposition, lack of intelligence, hateful conduct and food habit, excessive sexual indulgence and sleep.

2 Matsya

Cowardice, lack of intelligence, greediness for food, unsteadiness, fondness for constant movement and desire for water.

3 Vanaspatya

Indulgence in food and deficiency of intellectual faculties.[4]

Conclusion

Ayurveda advocates health not only as the fitness of physique but also as the wellbeing of soul, mind and faculties. So, the persons who prefer the attainment of the goal should follow the advice of this health science not only to cure the disease but also for the prevention of psychological and somatic

miseries. Shortly the way to pure knowledge is through a clear mind and the same clear food itself.

Ahara Suddhai Satva Suddhi Satva Suddhai Dhruvo Smruthim

The concept of Manasa Prakruti in Ayurveda should be elaborated with the help of modern psychology. Each individual has a different temperament. The descriptions of personalities available in Ayurveda are the simplest account of the genetically determined temperament of man. Manasika prakruti has significant implications as regard to the problems of mental health and psychiatric medicine [5]. Thus Susrutacarya says, kayanam prakrutim jnatva anurupam kriyam caret, that is the physician should first of all ascertain the prakriti of the individual and thereafter initiate the treatments suitable to him. Everybody should take Satvika ahara to attain longevity, health and prosperity.

Education and Learning is a strong instrument that can change the future of our world. Upgraded technology and total information system are playing a crucial role in developing new inventions in our education sector. The year 2020 has undoubtedly been one of the eventful years till now. Outbreak of the Corona Virus has changed the total predictions of the world. Impact of the Covid-19 is evident in all industries and sectors. Education Industry also faced huge challenges during this period. The conventional way of learning process has replaced and shifted to a new path. As this pandemic was an unprecedented scenario, many educators and students were unprepared to cope up with the new method of learning: the virtual classroom. This research is an attempt to analyse the changes due to Covid-19 and different aspects related to it. This is a study conducted with special reference Idukki District. Usually the people moving from Idukki to other places for the higher studies for overcoming the limitations but this pandemic force everyone to stay in their own places. E- learning is not very much possible in Idukki due to lack of reliability towards internet, technological issues, geographical and climatic conditions etc., Emerging importance of e-learning platforms and the major issues faced by places like Idukki is considered in this paper.

Keywords: Challenges, Covid-19 pandemic, Education, E-learning Platforms, Idukki District.

1. Introduction

Learning and education are the two key factors that can mould our career. Learning is a process of gaining knowledge through experience, practice and in education we are acquiring knowledge through teaching and interactions. Both processes can be developed through outside source and inner self. The medium can vary according to individuals, location etc. Education and learning began in prehistory, as adults trained the young in the knowledge and skills deemed necessary in their society. In pre-literate societies, this was gained orally and through imitation. The basic fundamentals of a structured society is forming on the basis of skills, culture, values, beliefs and knowledge which is

provided through education and learning. Education is passed through different stages like Gurukula, Informal Teaching, Formal Classes and virtual classrooms as of now.

The 21st century is a remarkable period for the education sector. As a result of the unexpected outbreak of Corona virus (covid-19) the entire world witnessed the changes in the total learning system and how the e-learning platform becomes the powerful medium of education. All the universities, schools and even kindergarten also forced to learn through the e-learning platforms. It was a drastic change that has happened in the entire world despite of geographic conditions, economic standards, social structure etc. But the main thing is the influence the practical implications of the e-learning is different from one another.

E-learning is a highly beneficial platform which is considered as a result of integration of technology and education. The unquestionable significance of e-learning in education has led to a massive growth in the number of e-learning courses and systems offering different types of services. Major prestigious universities like Oxford, Harvard, Yale and all other universities are trying to finish the semester exams. But the major question is 'Can online classes compensate the Campus or School experience?'. Digital literacy of teachers, faculties, students and parents, the mental state of participants in this platform, availability of reliable internet services in the particular place are some major considerations which is coming under this topic.

The first higher education institute to offer an online curriculum was CAL Campus, created in 1994. Shortly after, the University of Virginia Beach issued its first PhD through courses delivered entirely via email. Webcam, another technical innovation of the decade, profoundly replaced the nature of the relationship between teachers and students. Open source learning solutions become more democratic in 2000 and collaborative learning become a commonplace in educational institutions and universities. More than 40% of the 500 largest companies now use e-learning for employee training. Different types of e-learning are;

- Computer Managed Learning (CML)
- Computer Assisted Instruction (CAI)
- Synchronous Online Learning
- Asynchronous Online Learning
- Fixed E-Learning
- Adaptive E-Learning
- Linear E-Learning
- Interactive Online Learning
- Individual Online Learning
- Collaborative Online Learning.

All these online learning is happening in 21st centuries through the platforms like Coursera, Alison, Skillshare, Future Learn, Udemy etc. E-Learning platforms are mainly targeted on students and they are trying to provide content based education. Government initiatives towards digitalization are a major trend in the market. As we all know the current situation changed the traditional approaches towards education and it paved a credible growth in the market of e-learning industry.

2. Literature Review

Vishal Dineshkumar Soni in his paper titled as "Global Impact of E-learning during COVID 19" is discussing transformations in the education system due to this pandemic. This is focus attention on

the topics like Role of e-learning in covid-19, Global transition to online education, Changes in e learning and beneficiaries of e-learning, learning platforms etc. Significant growth is witnessed by the world in online education system by the potential users, providers and through several platforms. Recorded report states that Microsoft team users were 750 as of 10th March but by 24th March it has risen up to 138698 which is indeed a significant growth. The pandemic replace the conventional approaches of education existed in academia by introducing some beneficiaries and advantages for the students, teachers, research scholars etc. The e-learning resulted disruptive shift and it generated some challenges in the education but due to the regular use, necessity and implementation of new programmes are helping a lot to cover the barriers. Drastic changes in the total system need implementation of strategies to grow. Otherwise unequal gap and many other problems many emerge in our educational industry.

Fouzia Shersad in his research paper titled as “Managing Risk of E-learning During Covid-19” aims at structuring multiple facets of e-learning risks in a way that will be practicable for educators and education administrators to assess and plan appropriate measures. Major concerns of this paper are risk management, cyber security in education, security system and higher studies. As a result of the analysis they found out some general risk related to e-learning such as internet traffic, lack of readiness, poor practical skills, lack of student engagement and increasing cyber security. Systematic planning is a key tool that helps to deal with unprecedented events in future also.

Paul Agu Igwe in his paper “Higher education and Students Experience Under Covid-19” giving more emphasize on the Higher Education and experience of students. “Education stakeholders and policy-makers need to re-examine the relevance of education in the current global economic, social, health and technological changes. Adequate funding is required to train teachers, provide an enabling learning environment and professional development of teachers. Governments in developing countries need to go into a collaborative funding arrangement with digital and mobile technological operators to provide students and staff with free access to internet and e-learning platforms in the form of vouchers and codes. Special funding must be provided to higher education institutions to provide online teaching and learning platforms that improve student engagement, create opportunities for one-on-one interactions and offer accessibility anytime and anywhere, thereby enhancing students’ experience. Technologies like Blackboard Collaborate, Moodle, and Google meet, Zoom and MS Team and other virtual classrooms offer virtual solutions that deliver a level of engagement that makes learners forget they’re not in a physical classroom”.

Ravi Rai Dangi & Mathew George made a study titled as “Psychological Perception of students during Covid-19” is dealing with outbreak in India on the mental well-being of the students during the time of pandemic. Most students were anxious during this time and stressed. Increased anxiety can affect negatively to psychological, emotional and behavioural state of the students. If psychological state is not in equilibrium, then students could not be able to concentrate on their studies. Investigators recommends that government authorities and educational institutes can take collaborative steps to solve these various problems in upcoming near future.

Syama U S in his paper titled as “The Evaluation of Efficiency of Online Classes during the Period of Covid-19” is more focused on efficiency and effectiveness of online classes and its outcome. The responses help to understand the value of education through virtual classroom. It is different from one person to another and it’s depends on the student’s engagement.

3. Research Methodology

This research is based on 159 responses and aims to systematically and accurately describe population, situation or phenomenon with the help of descriptive sampling. The total population is divided into smaller groups or strata and completed the sampling process with the help of stratified sampling.

Research design specifies the methods and procedures for conducting a particular study.

Types of Research Design

Research design has been classified in different ways, such as

- * Exploratory Research Design
- * Descriptive Research Design
- * Casual research Design

Descriptive Research Design:

I have chosen a descriptive research design that is well structured. The objectives of such are to answer the “who, what, when, and how” of the subject under investigation.

- * Field Studies
- * Survey

I have taken survey research because a major strength of survey research is its wide scope. Detailed information can be obtained from a sample of a large population. Besides, a sample survey needs less time than a census inquiry.

4. Source of Data

The study was conducted based on the collection of primary and secondary data;

Primary data

Primary data is the data collected for the first time by the researcher. Primary data has not been published yet and is more reliable, authentic and objective. Primary data has not been changed or altered by the researcher. Therefore, its validity is greater than secondary data. The sources for primary data are limited and at times it becomes difficult to obtain data from primary sources because of either scarcity of population or lack of cooperation.

The sources are;

- *Questionnaire
- * Survey
- * Telephonic Interview
- * Observation
- * Experiments

Secondary data

Secondary data is the data which are collected already by some other person. It is the second hand information. Data collected from a source that has already been published in any form is called secondary data.

The sources are;

- * Textbooks
- * Journals
- * Newspapers and Magazines
- * Published sources
- * Internet

5. Sample Design

To carry out the study

Area of Research –Idukki

Sample Size – 159 Respondents are chosen so that it could give a fair response to achieve our objectives and also could be finished within the stipulated time limit.

Type of Sample Design

The type of sampling that was carried out was probability (convenience) sampling due to limited resources available.

In non-probability sampling, I have chosen simple random sampling because this was the best sampling method to do a market survey. On another aspect, to cover all consumers in Kottayam.

6. Method of Data Collecton

Primary source of data:

Questionnaire:

Keeping in view of the objectives of study, a questionnaire (as given Annexure) was prepared. All questions are small in size and arranged logically. The language is simple to understand.

Interview:

Information was also obtained by conversation with some customers. Some of the customers were interviewed personally.

Secondary source of data:

The second information is taken from company document available on websites. The information from other related journals and industry association's sites have also been viewed.

7. Drafting Questionnaire

I have collected details from the students and teachers in India through a questionnaire by using google sheet. The questionnaire consists of open-ended questions and 5-point scale questions and applied Likert scale also.

8. Objectives

- To analyse the impact of Covid-19 in education sector.
- To acknowledge trends in virtual learning platforms.
- To understand the influence of e-learning platforms in student’s career.
- To examine the importance of new phase of education system.

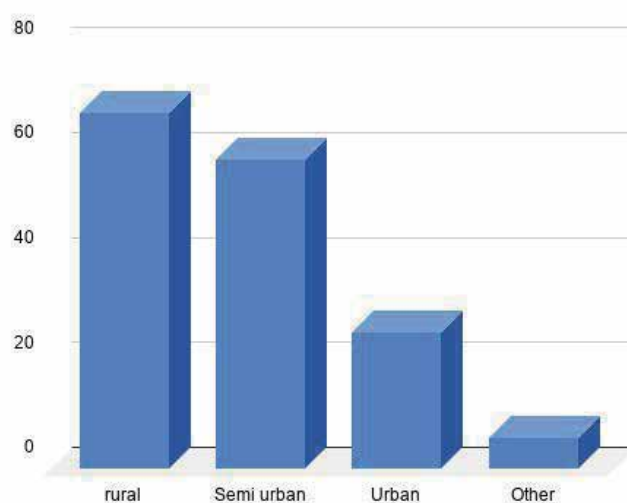

9. Data Analysis and Interpretation

The Collected data from a survey are represented with the help of charts. All the questions are regarding to the changes in the time of pandemic and others attitude towards the changes. This survey has focused both students and faculties belongs to different age category.

9.1 Age of the participants

9.2 Area of living

9.3 Educational Status

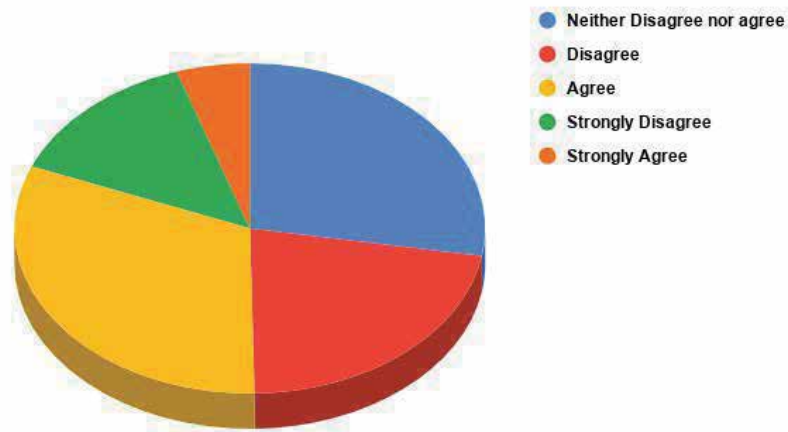

9.4 Gender

9.5 Do you think that there is a relationship between e-learning and student motive?

9.6 How much you are agreeing with the virtual classroom?

9.7 Most common e-learning platforms using for online classes

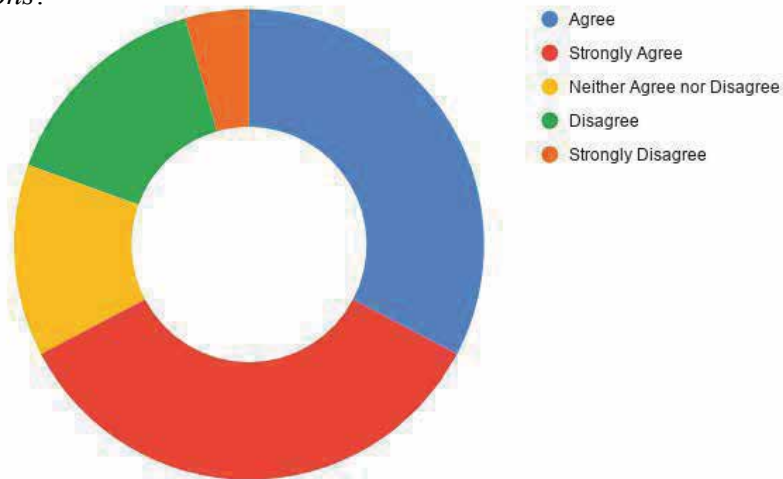

9.8 Other e-learning platforms

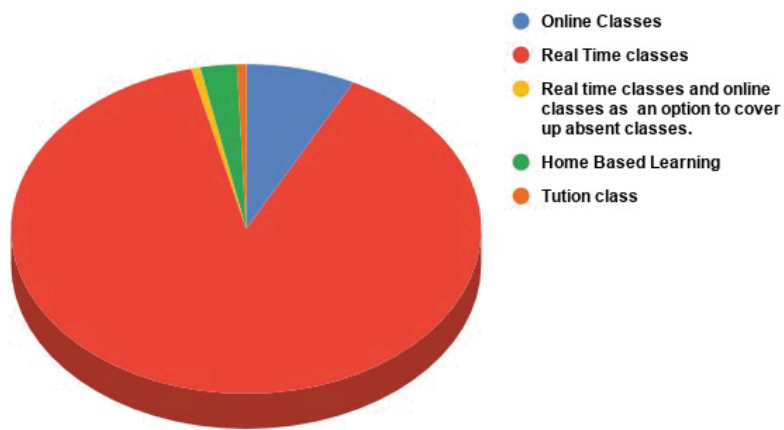

Count of Specify the e-learning platforms if you have put tick on 'Others'.

9.9 Do you agree with the relationship between character development and classroom sections?

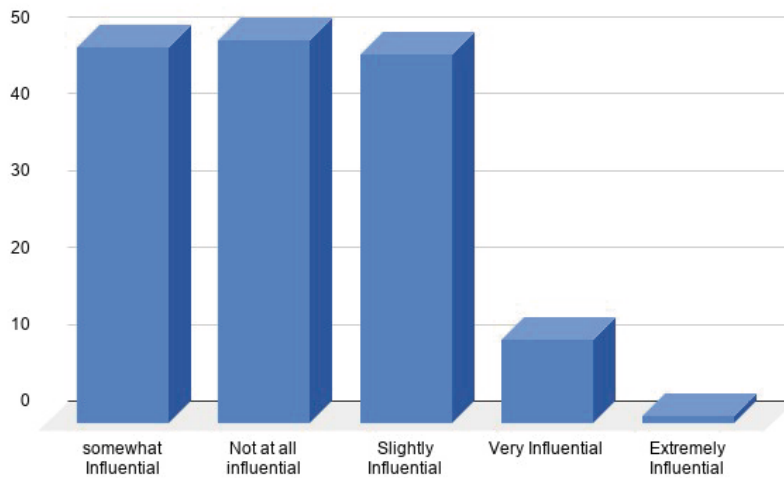

9.10 Which one is your favourite mode of class?

9.11 Are you supporting collaborative study (offline & online) in future?

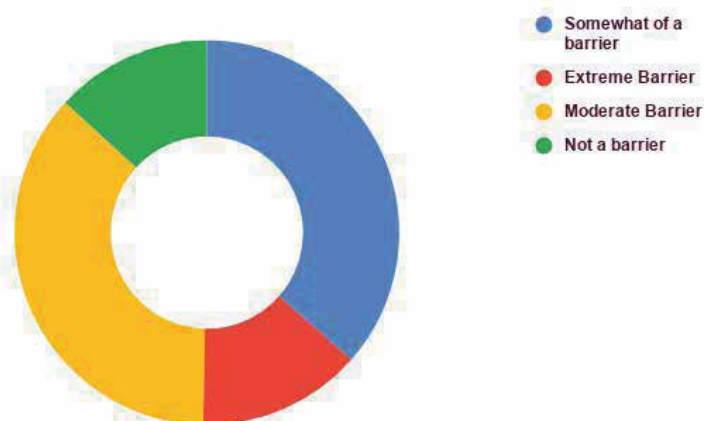

9.12 How much you are influenced by advertisements related with the educational fields in the time of covid-19 spread?

9.13 Do you believe that outbreak of covid-19 helps to develop a trust in the mind of students and teachers towards the virtual learning platform?

9.14 New phase of education is standing as barrier against total development of student?

9.15 *Have you ever accessed a paid online service for the betterment of your education?*

9.16 *Did you ever felt any kind of disturbances while you are attending online classes due to network issues?*

9.17 *Virtual classes are comfortable when compare to the real time classes.*

9.18 Have you ever felt any kind of sufferings due to the lack of electronic gadgets?

8. Results

- Out of 159 responses, 64.8% of the respondents were female and 35.2% were male.
- Age group of the respondents are;
 - *73.6% - 19-23 years
 - *18.9% - Above 23
 - *5.7% - Between below 12-18 years
 - *1.9% - Below 12 years
- Out of the 159 responses 42.8% lives in rural areas, 37.1% in semi-urban areas and 16.4% lives in urban areas.
- 95% of the respondents were students and 5% of the respondents were faculties.
- 43% believes that there is a relationship e-learning and student Motive.
- 31.6% people agree with the virtual classroom, 21.5% people are disagreeing Virtual class room and 27.8% neither agree nor disagree with this.
- There is a hike in the use of e-learning platforms.
 - *77.2% - Google Meet
 - *44.9% - Zoom
 - *13.3% - Microsoft Teams
 - *30.4% - WhatsApp
 - *Other mode of study includes Telegram, Cisco WebEx, Moodle, Google Classroom etc.
- 61.9% believes that there exists relationship between classroom section and character development.
- 88.6% support real Time Classes and 7.6% supporting online classes.
- 29.7% favour collaborative (offline & online) in future.
- 38% slightly and strongly influenced by the advertisements in the field of education in the time of Covid -19
- 44.2% believes that outbreak of Covid- 19 helps to develop a trust in the mind teachers and students towards virtual learning platform.
- 86.7% believes that new phase of education is standing as a barrier against total development of a student.

- 74.1% didn't access any paid online service for the betterment of education and 25.9 % accessed the paid service.
- 86.1% felt disturbances while attending online classes due to network issues.
- 70.2% think that real time classes are comfortable than virtual classes.
- 43.7% have felt sufferings in study due to the lack of electronic gadgets.

9. Suggestions

- Covid -19 made a strong impact in education sector in all aspects and its effects are different from one person to another and it depends on different parameters.
- Use of virtual learning platforms helps to increase the trust towards them
- The pandemic period results a competition among the e- learning platforms.
- Most of the people are still comfortable with the Real time classes and its benefits,
- Access to network and lack of gadgets and materials are some major existing problems in the new phase of education.
- Most of the people are believes that new phase of education has resulted a change in the student motive and character development due to the unexpected shift from the convenient way

10. Conclusion

The COVID-19 pandemic has affected educational systems worldwide, leading to the near-total closures of schools, universities and colleges. Most governments around the world have temporarily closed educational institutions in an attempt to contain the spread of COVID-19. Technology may play an important role in the lockdown period like study from home and work from home. In India, some private schools could adopt online teaching methods. Low-income private and government school may not be able to adopt online teaching methods. And as a result, there will be completely shut down due to no access to e-learning solutions. This study helps to find out the impact of Covid -19 on education.

The possibility of libraries has been changed by the Information and Communication Technology. In cutting edge period each and every library is steadily getting digitalization. The automated combinations, organizations and structure to help profound established learning, investigate, scholarly correspondence similarly as shielding and conservation of our recorded data are remembered for the high level library. The procedure of democratization of data is likewise engaged with it. In this paper, the concept has been given about the variables that will require the conventional libraries to get digitalization, just as the definition, need, assets of the digital library, necessities for advanced library and qualities, preferences and inconveniences of computerized libraries. To depict the job of a custodian in the new condition the accentuation is additionally set up in this paper.

Keywords: - Electronic libraries, Uses of Electronic Libraries, Digital libraries, kind of Digital libraries, functions of digital libraries

1. Introduction

Our overall population has become a coordinated society wherein all circles of human development has been used comprehensively to record, store, and dissipate the information in the automated design by using advancements. The world has almost changed over into an overall town in view of its impact. There is an effect in the information business in view of the requirements in the job of Libraries is likewise changing to fulfil the need put on them. The conventional libraries ought to be created as a well prepared and interconnected digital libraries to satisfy the need of new-age whose interest for data is never. The idea is acknowledged everywhere throughout the world in the 21st century that the data is for use and all then the library ought to be for all. For each one of the individuals who look for data, the libraries must get all-inclusive open.

2. Definition

There are various implications of a "digital library," as a conversely "electronic library" and "virtual

library" terms are routinely used. The term Digital Library has a combination of expected ramifications, going from a digitalized variety of material that one may find in a standard library through to the arrangement of all high level information close by the organizations that make that information accommodating to each and every conceivable customer. A digital library is an enormous database for the individuals who are taking a shot at hypertext condition which bolsters the full life pattern of creation, stockpiling, safeguarding, scattering and utilization of information, data and information.

3. Role of Digital Library:

The approach of digital libraries has changed the job of the library and data Professionals, just as the necessary client abilities. It is along these lines imperative to get what, in truth a digital library is: Digital Library, a huge worldwide and conveyed information archive, which is upheld by various databases and dependent on scholarly innovation, is a library software that gives the clients gigantic and composed data and information base that effectively search and use. It is mostly a computerized arrangement of data source received by the current cutting edge, which is a huge scope of information focus and advantageous for use past the real limits. The digital library has been characterized by numerous points of view. An advanced library, similar to any library, is help that depends on standards of choice, procurement, access, the executives and protection of data assets, implied for a particular customer network".

4. Commencement of Digital Libraries:-

The idea of advanced libraries is established in the deep-rooted fantasy about making a virtual library. Among early endeavours, one can cite the endeavours made by Paul Otlet and his associates in 1930s to configuration works comparatively to the present hypertext and hypermedia system. In 1945 Vannevar Bush¹³ put forth a few attempts to give a thought of interfacing the whole human information. He gave an idea of Memex machine, which utilized microfilm perusing procedure to recover put away data. Be that as it may, the enthusiasm for computerized libraries, both academic and expert, became quickly just in the 1990s. As expressed before, advanced library improvements in the USA occurred for the most part throughout look into drove fundamentally by the software engineering network that focused on planning and creating innovations for different digital library assortment and administrations.

5. Categories of Digital Libraries

- * Computerized libraries can be gathered in the accompanying ways'
- * Digital libraries created in USA as a major aspect of (Digital library activities)
- * Digital libraries created for eLib (electronic libraries)Program in UK
- * Digital libraries worked by singular foundations
- * Digital libraries that are a piece of National Libraries
- * Computerized libraries that are a piece of colleges, or by period, or by a nation of their beginning.

6. Objectives besides utilities of Digital Libraries:-

- * To gather, store, compose and get to data in advanced structure using correspondence chanel.
- * To meet the prerequisites of benefactors by offering better types of assistance.
- * To offer customized and proficiently review types of assistance.
- * To have enormous digitized databases.

- * To spare time of library staff by maintaining a strategic distance from routine occupations.
- * To give an intelligent perspective on all data inside a library in any design.
- * To serve generally scattered networks all through the system.
- * To limit monstrous capacity and space issue of enormous libraries.
- * To decrease cost engaged with different library exercises.

7. Electronic Library:-

7.1 Definitions:-

* Z of Library Jargon of oxford Brookes University characterize the term E-library as, Section of the Library Web pages which gives admittance to information bases, electronic diaries, electronic books and electronic papers.

* Public Diet library, Japan is characterized the "electronic library idea" as "a library which gives essential and auxiliary data electronically through correspondences organizations and the reason for this reason." Putting accentuation on the library as a method of administration, electronic library administration, remembering for library administrations, is comprehensively characterized as "administration which empowers library clients to straightforwardly get to electronic information by means of media communications organizations."

7.2 Advantages of Electronic Library:-

- * Presently the scholarly libraries are moving to the conventional print assets into e-asset and keep up as Institutional storehouse. Those assets are postulations and expositions and other inventive academic library
- * Work done by staff or understudies. There wellsprings of institutional store are circulating through web or intranet to
- * Its client local area. The advantages of e-library for the accompanying:
- * When utilizing electronic data sources part of advantages are get by the clients that they are:
- * E-libraries are the best instrument for giving on the web assets to explore which will make simple to its clients.
- * Review search is simple and generally helpful than print asset.
- * Proficiency is increments when looking through made by the instructors.
- * Looking of file is likewise simple.
- * It upholds for looking with the blend of keywords.
- * While scanning made by supporters for their venture to recover a reasonable measure of substance, rapidly and without any problem.
- * Arrangement for synchronous access of numerous document.
- * E-libraries encourage to its benefactors for research arrangement.
- * Arrangement for print out and saved the down burden things for future references.
- * The distance students are additionally looking through their necessity from e-library.
- * E-Library gives the advantage to coordinated hunt to word reference, reference book, chronological registries, and so forth through the reference work area.
- * The least complex usefulness like Point-and-snap advances the clients interest.

8. Cutting-edge Resources:-

Advanced assets might be characterized extensively as any electronic diaries, magazine, e-zine, web-zine, bulletin or kind of e-serials productions, which is accessible over the Internet and can be gotten to utilizing various innovations, for example, www, gopher, FTP, telnet, email or rundown server and so on. E-Journals are the periodicals, a standard or unpredictable moderate unit made accessible in an e-position either on a static medium or using PC systems. Applying Ranganathan's Five Laws to the computerized assets to this examination.

- * Digital assets are for use.
- * Each utilizes their computerized assets.
- * Every advanced asset of its client.
- * Save the hour of the client.
- * The advanced asset is a developing living being.

9. Categories of E-Resources:-

The e-assets are fundamentally segregated in two noteworthy sorts are:-

- * Online e-resources, which may join, for instance, e-journal (Full substance and bibliographic), advanced books, on-line Databases and Web goals
- * Other electronic resources may join, for instance, CD ROM, Diskettes
- * Other reduced PC databases.

10. Classes of E-Journals:-

Online Journals

Electronic diaries come in numerous sorts. Some of them are conventional paper diaries made accessible electronically, others are straightforward determination or simply the chapter by chapter guide of the paper diaries and still others have no proportional paper duplicates.

CD ROM Journals

These are full content diaries distributed and dispersed as CD ROM with ordinary updates, alongside search software to access and print. Connection online diaries, by far most of CD ROM based diaries are the electronic renditions of printed diaries for example

- * Meeting procedures and diaries of IEEE
- * Conference procedures and diaries of ASME Kling and Mcklim (1997)17 recognized e-diaries into four sorts in particular,
- * Pure electronic diaries - Journals whose content initially dispersed just in computerized structure.
- * Electronic Print Journal Journals essentially disseminated electronically, however, may have constrained dispersed in paper structure.
- * Print Electronic Journals
- * Journals essentially disseminated in paper structure but on the other hand, are disseminated in electronic structure.

* Print, Electronic Journals, Journals that are started with equal paper and electronic releases that might be generally dispersed.

11. The dissimilarity between conventional and digital libraries

Sr. No	Conventional libraries	Digital libraries
1.	Print collection	All assets in computerized (sight and sound) structure.
2.	Stable, with moderate evolution	Dynamic and vaporous
3.	Singular articles not legitimately connected With each other.	Individual objects are legitimately connected.
4.		
5.	Less/Minimum assortment of data	Large assortment of information
6.	Scholarly content with the validation process, More than an academic substance with different approval forms & Constrained passages and unified management.	Unlimited passages, disseminated assortments and The physical and legitimate association might be for all intents and purposes
7.	One way interactions	Dynamic constant discourse
8.	Free and widespread access.	Free just as a charge based.

With the presence of PCs, the thought focused on colossal bibliographic databases, the now notable online recuperation and network programming that are a bit of any contemporary library. Addition in the amount of customer and their different needs have made modem libraries to apply new information and correspondence advancement. On account of this, there is a general need and example to accumulate sort out regulate, secure and fitting information in the mechanized structure. Exactly when PCs were related to gigantic frameworks molding the Internet, the thought progressed again, and explore went to making libraries of mechanized information that could be gotten to by anyone from wherever on the planet. Articulations like "electronic library," "library without dividers" and, most as of late, "advanced library," all have been used on the other hand to delineate this wide thought.

12. Few imperative features of the digital libraries are

- * Digital Libraries join both propelled groupings and customary, fixed media collections. So they encompass both electronic and paper materials. So electronic libraries support blended media content.
- * Digital Libraries will similarly fuse propelled materials that exist outside the physical and administrative constraints of anyone advanced library. Henceforth electronic libraries give access from huge information varieties.
- * Digital Libraries will require both the capacities of clerks and well as those of PC scientists to be sensible.
- * Focus on offering access to fundamental (or complete) information not simply proxies or records.
- * Digital libraries are System open Give simple to utilize interface.
- * Use decisive portrayal of record (for example labelled little content) what's more or as against picture, postscript, and so forth shapes.
- * Digital libraries are giving one of a kind referencing of computerized objects.

* Digital libraries Bolster conventional library strategic assortment, improvement, association, Access and conservation. Digital libraries are offering Help propelled search and recovery.

13. Inspirations behind Digital library

- * For improvement of assortment, store, and arrange, data in the advanced structure.
- * To give require data financially to all clients.
- * To increment co-usable endeavors in an asset, PC, and correspondence systems.
- * To increment correspondence and participation between instructive foundations.
- * To take a position of authority in the age and scattering of information.
- * To fulfilled distinctive data needs and prerequisite of various clients.

14. A serving of the chief State-of-the-art features, complications and concerns attracting the deliberation of in this region include:-

- * High bandwidth PC arrange to support productive sight and sound archive move.
- * Open correspondence conventions (customer server, for example, z39.50for IR).
- * Information gets to instruments (peruse, show and search devices).
- * Meta database (information-based that depict and give connects to different databases/Data sources.
- * Electronic distributing instruments (individual, institutional, distributor).
- * Data pressure.
- * Digital stockpiling. Scanning and transformation advance.
- * Media coordination advances (multi-media).
- * Advanced recovery, ordering, and regular language preparing, directing and sifting.
- * Document portrayal and portrayal norms (for example SGML).
- * Inter-operability (how do various computerized libraries connect).
- * Privacy, validation and security

15. Themes of attentiveness of the Digital Library

The positive aspect of computerized libraries are:-

- * Round the clock accessibility: Digital libraries can be gotten to whenever, 24 hours per day and 365 days of the year.
- * Multiple gets to similar assets can be utilized simultaneously by various clients.
- * Enhanced Information recovery: The client can utilize any inquiry term roaring to the word or expression of the whole assortment. The computerized library will give very easy to use interfaces, giving snap capable access to its resources.
- * Preservation and preservation: A precise of the first can be made any number of times with no corruption in quality.
- * Unlimited extra room at lower cost: Whereas customary libraries are constrained by extra room, computerized libraries can store significantly more data, just because advanced data requires almost no physical space to contain them. At the point when the library has no space for expansion, digitization is the only solution.
- * Networking: A specific computerized library can give the connection to some other assets of other advanced libraries effectively along these lines a consistently incorporated asset sharing can be accomplished.

* Cost: The expense of keeping up an advanced library is a lot of lower than that of a conventional library. A conventional library must go through huge entreties of cash paying for staff, the book looks after, lease, and extra books. Computerized libraries get rid of these fees.

16. Problems of the Digital Library are:-

Preservation:- Due to innovative turns of events, a computerized library can quickly get outdated and its information may become inaccessible.

Skill individual:- If we need to work in an advanced framework we need to ability people in working and looking after digital libraries.

Effect of Technology:- The advanced library entirely reliant on media transmission and PC. As innovation comes in the market the computerized framework should change or receive that technology.

Security issue:- When our computerized framework is associated with the Internet the serious issue is the security to forestall the unapproved get to and to keep the data from infection is the significant undertaking in digital system.

18. About Author:- The author (Pankaj Bhagat) is working as Librarian/teacher in very prominent group of colleges based at Punjab, he has published 23 research papers, one book, 7 book chapters, 8 conference proceedings, delivered lectures on national and international conferences, seminars and has participated in 60 plus conferences, seminars, workshops, and training programs at national and international level. Got best article award, the author has done MLIS, M.B.A., PGDCA, certified courses on research methodology, Ph.D. (Pursu.) fourth year, significant experience in research and research techniques.

The author 2 (Priyanka Negoi) is working as Librarian in Uttarayan College of Education, Vill. Jatrapur, Dist. CoochBehar, (West Bengal). She has done MA in Political Science, B.Ed., M.Ed. and BLIS, MLIS and has five year experience in as librarian, she has published good number of National and International Conference Proceedings and Edited Books.

Role of Breathing Exercises in Post Covid Setting

Premkumar K.

Professor & HoD

Dept of Physiotherapy

College of Paramedical Sciences, EMCHRC, Perinthalmanna, Malappuram

Email: premvellila@gmail.com

The COVID-19 is an ongoing pandemic of coronavirus disease 2019 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). WHO reported over 128 million individuals confirmed COVID-19 globally till March 2021, resulting over 2.8 million deaths. Approximately 20% of asymptomatic people who test positive for COVID-19 will remain symptom-free over time. An electronic literature review of COVID-19 studies propose that most of asymptomatic patients should be considered pre-symptomatic resulting significant damage in respiratory system, often leads to pneumonia and even acute respiratory distress syndrome (ARDS) a severe lung injury. Recovering lung function is possible but can require therapy and exercises for a month after the infection is treated. Breathing exercises is beneficial for patients with mild symptoms of COVID-19. Exercises like breathing control, pursed lip breathing, belly sleeping, walking, and thoracic expansion are good to keep the lungs healthy. These exercises should be followed in order to maintain the oxygen levels in the body and also to restore the lung functions.

How breathing exercises can help

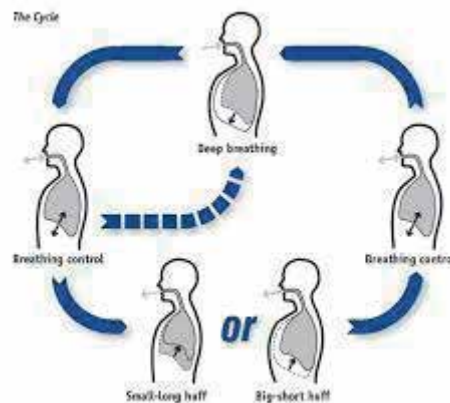

Healthy lungs, breathing is natural and easy and allows breath in and out with your diaphragm doing about 80 percent of the work to fill your lungs with a mixture of oxygen and other gases and exhale out. When the diaphragm muscle is weak, body starts to use other muscles in the neck, back and chest for breathing. This translates into lower oxygen levels, and less reserve for exercise and activity. Regularly practice breathing exercises can help the lungs to get rid of accumulated stale air increase oxygen levels and get the diaphragm to return to its job of helping you breathe. COVID-19 along with co morbidities such as diabetes, chronic respiratory disease and cardiovascular diseases are at a higher risk of developing infection. COVID-19 patients' experiences short of breath and oxygen saturation begins to fall. Regular breathing exercise and physical activities will improve lung problems and general conditioning. The scientific evidences still unclear but pulmonologist and rehabilitation specialists suggests breathing techniques will helpful to restore respiratory muscle strength and lung functions.

1. Breathing control

Breathing control is breathing gently, using as little effort as possible.

- a. Breathe in and out gently through nose or through mouth
- b. Breathe out through mouth, purse lips like are blowing out a candle
- c. Gradually try to make the breaths slower

d. Closing eyes to focus on breathing and to relax .It is very important to do breathing control in between the more active exercises of ACBT as it allows airway to relax.

2. Diaphragmatic Breathing (Belly Breathing)

Deep breathing restores lung function by using the diaphragm. Breathing through the nose strengthens the diaphragm and encourages the nervous system to relax and restore itself.

Recovering patients from COVID-19, the deep breathing exercise are given into phases of individual ability.

Start with Phase 1 increase repetitions or move to the next phase when you can complete the exercise without feeling breathlessness.

Phase 1: Deep Breathing

Lie on your back and bend your knees so that the bottoms of your feet are resting on the bed.

Place your hands on top of your stomach or wrap them around the sides of your stomach.

Close your lips and place your tongue on the roof of your mouth.

Breathe in through the nose and pull air down into your stomach where your hands are. Try to spread your fingers apart with your breath.

Slowly exhale your breath through the nose.

Repeat deep breaths for one minute.

Phase 2: Deep Breathing While on Stomach

Lie on your stomach and rest your head on your hands to allow room to breathe.
Close your lips and place your tongue on the roof of your mouth.
Breathe in through your nose and pull air down into your stomach. Try to focus on your stomach pushing into the mattress as you breathe.
Slowly exhale your breath through your nose.
Repeat deep breaths for one minute.

Phase 3: Deep Breathing While Sitting

Sit upright on the edge of a bed or in a sturdy chair.
Place your hands around the sides of your stomach.
Close lips and place your tongue on the roof of your mouth.
Breathe in through your nose and pull air down into your stomach where your hands are. Try to spread your fingers apart with your breath.
Slowly exhale your breath through your nose.
Repeat deep breaths for one minute.

Phase 4: Deep Breathing While Standing

Stand upright and place your hands around the sides of your stomach.
Close your lips and place your tongue on the roof of your mouth.
Breathe in through your nose and pull air down into your stomach where your hands are. Try to spread your fingers apart with your breath.
Slowly exhale your breath through nose.
Repeat deep breaths for one minute.

3. Gentle breathing

Relax your shoulders and body.
Gently breathe in and out in a relaxed manner

4. Pursed Lip Breathing

Take in a medium-sized breath.
Open your mouth breathes out forcefully and quickly engages your chest and stomach muscles.
Repeat once or twice and end the exercise with the exhaling huff, with pursed lips.

5. Huffing

A huff is exhaling through an open mouth and throat instead of coughing. It helps move sputum up airways so that you can clear it in a controlled way. To “huff” you squeeze air quickly from your lungs, out through your open mouth and throat, as if you were trying to mist up a mirror or your glasses. Use your tummy muscles to help you squeeze the air out, but do not force it so much that you cause wheezing or tightness in your chest. Huffing should always be followed by breathing control. There are two types of huff, which help to move sputum from different parts of the lungs.

The current education system focuses the online related teaching-learning methods. In particular, all the learners want to free, open, accessible, and legal educational resources. The open educational resources fulfill all the related academic problems to the learners. The study's main objective is to determine the level of usage of open educational resources and determine the level of performance in education among the state universities of Tamilnadu research scholars. A sample of 300 research scholars from 22 state universities in Tamilnadu state is selected randomly for the study. The study conduct between 17/10/2020 to 26/12/2020 by using a survey method. Data were analyzed using percentage analysis and t-test. Findings reveal that 30% of the state university research scholars have a high level of open educational resources usage, and 24 % have a high level of education performance. Results also imply a significant difference in the utilization of open educational resources among male and female state universities research scholars. There is no significant difference in education performance among male and female state universities research scholars concerning gender. The COVID-19 epidemic and paralysis have questioned the education of migrant workers and their children. Open educational resources are a sustainable education system in the future, even in a virus outbreak, storm, flood, world war, etc.

Keywords: Open Educational Resources; Open Educational Practices; Research Scholars; Creative Common

1. Introduction

‘Open Educational Resources’ designed to facilitate learning and teaching for free[1], [2]and easy use[3]–[5] by all people with Creative Common license[6], [7]. OER is an open license material that everyone can use for learning[6], [8], [9]. Creative Common (CC) license is also a profitless organization system that can issue free licenses[9]–[11]. It is permitted to the learners in the 5R activities [12](see Fig. 1):

Fig. 1. 5R's of Open educational Resources

Retain is called Prepare and reserve copies of the content. Reuse called to use the content frequently anywhere, anytime, anyplace. Redistribute is called Change the content and can be visible in all languages. A remix is called Link the content in all resources, and Revise called Exchange the merged content with other users.[9], [12], [13].

Retain is called Prepare and reserve copies of the content. Reuse is called as again and again use the online resources anywhere, anytime, anyplace. Redistribute is called Change the content and can visible in all languages. The remix called to link the content in all Open Educational Resources (OER) is educational practice and research materials on any medium, digital or otherwise, that reside in the public domain. An open license allows access, use, adaptation, and redistribution without cost by others with no or limited restrictions used to support education to freely access, reuse, modify, and share[16], [17]. These guidelines summarize the key issues and suggest integrating open educational resources into higher education[18], [19]. The purpose is to encourage governments and institutions to invest in systematic production, adaptation, and use of open educational resources and bring it into the mainstream of higher education to improve curricula and teaching quality and reduce costs[20]. Given the potential of OER to improve higher education systems, UNESCO[21]–[23] and the Commonwealth of Learning have developed these Guidelines[6], [24], [25], , after extensive consultation with stakeholders in all regions of the world, to support governments, educational institutions/provider's superiors, academic staff, student bodies, and guarantee/accreditation bodies and quality recognition. Open Educational Resources are composed of educational content, tools, implementation resources, and external links[26]. Indian free educational resources is a generic denominator that includes courses, programs curricula, didactic modules, student guides, textbooks, research articles, videos, podcasts, assessment tools, interactive materials (such as simulations), databases data, software, and applications[19]. All the free educational material design for use in educational practices[27]–[31].

The university grants commission was categorized as some universities are under the state universities of Tamil Nadu in India. Presently, 22 universities list under the state university of Tamil Nadu in India. In the state universities of Tamil Nadu, approximately 12,000 research scholars in the current academic year. The Tamilnadu state universities are Alagappa University, Anna University, Annamalai University, Bharathidasan University, Madaras University, Madurai Kamraj University, Manonmaniam Sundarnar University, Mother Teresa Women's University, Periyar University, Tamil Nadu Fisheries University, Tamil Nadu Music and Fine Arts University, Tamil Nadu Open University, Tamil Nadu Teacher Education University, Tamil University, Tamilnadu Agricultural University, Tamilnadu Dr. Ambedkar Law University, Tamilnadu Dr. M.G.R.Medical University, Tamilnadu National Law University, Tamilnadu Physical Education and Sports University, Tamilnadu Veterinary & Animal Sciences University and Thiruvalluvar University.

2. Significance of the Study:

Open educational resources are very much influencing the lifestyle of the people. People are using the books and other materials like Radio, TV, computers, and the Internet to develop their lifestyle[32]. It impacts the lives of both young and old. The rise of open educational resources has created a new cultural force where educational functions rival those of the school. It becomes a necessity in almost all fields of life, including education, family, and recreation. In modern society, open educational resources are very much impacting the adolescent[33]. The present-day children are living in an altogether different world than that of their parents. There is a big gap separating the previous generation from the present living conditions. Open educational resources have emerged as prominent and influential components of modern society. The development of open educational resources and education is interwoven in so many ways that one's discussion is incomplete without reference to the other. Education, in the curriculum, provides certain values that are not provided by any other subjects. All the school subjects are taught because they provide liberal education; they are part of the equipment and preparation for life, which we expect the school to give to its pupils to play their part in the community as intellectual citizens.

3. Objectives of the Study

- 1) To determine the level of usage of open educational resources among state universities of Tamilnadu research scholars.
- 2) To find out the level of performance in education of state universities of Tamilnadu research scholars.
- 3) To find out the significant difference, if any, in the usage of open educational resources concerning gender
- 4) To find out the significant difference, if any, in performance in education concerning gender.
- 5) To find out the significant relationship between open educational resources and performance in Tamilnadu research scholars' state universities.

4. Null Hypotheses

H0:1 There is no significant difference between male and female state universities of Tamilnadu research scholars concerning the usage of open educational resources.

H0:2 There is no significant difference between male and female state universities of Tamilnadu research scholars concerning education performance.

H0:3 There is no significant relationship between usage of open educational resources and performa-

nce in Tamilnadu research scholars' state universities.

5. Review of Related Literature

The researchers follow the new literature review model and take the 2017-2021 period published research and review articles for this related literature study.

Table 1. Related Literature Review (2017-2021).

Author & Year	Aim/ Objective	Methodology		Result/ Findings & Future Research
		Sample Size/ Objective	Design/ Tools	
Singh & Chauhan, 2017	This study explores teacher educators' awareness towards MOOCs on conceptual understanding, usability, digital resources needs, open educational practice, and policy.	This survey sample size is 156 teacher educators.	This research was design with an awareness scale with the descriptive analysis used for this study.	Studies show that teacher educators have to select MOOCs' adequate knowledge and provide teacher educators with the facilities to develop and incorporate MOOCs into their everyday practice[34].
Joshith, 2020	This research paper examines awareness of Open Educational Resources and MOOC programme for Secondary level Teachers.	The study has undertaken 300 secondary education level teachers—the experimental study undertaken 30 samples for each control group and experimental group.	The study adopted both survey and experimental methods. The investigators conducted a Pre-test and post-test. They analysed with percentage, t-test, and effect size analysis..	The study showed that the population of high school teachers still has no understanding of OERs and MOOCs. It also has been demonstrated to promote teacher professional growth through proper exposure to open educational resources[35].
Nipa & Kermanshachi, 2020	The primary objective is clustering the utilisation	A sample size of 19 aspects of students & industry	One classroom participated with the internet based virtual OER	The research findings will encourage educational institutions to utilize avail-

	of OER resources for engineering and non-engineering students.			able funding resources to invest and install OER content. 78% of learners used mobile devices such as computers and electronic notebooks to share content. The second-largest system used to access the course documents has been identifying as smartphones (11 percentage usage). 19 percentage of learners chose a personal desktop computer to practice for academic studies. Only a few learners used the lesson plans' written materials[36].
Santiago & Ray, 2020	The objective of this paper is to describe programs that support OER publishing in academic libraries. Insights, opportunities, and challenges are concerning the broader open education movement.	Case study: the University of Houston and the University of Washington.	This paper provides two case studies describing the development of OER publishing programs at large, public research universities –Each program takes an Author DIY approach to publishing support and is in the early years of supporting OER adoption and creation.	They illuminate challenges and opportunities for librarians supporting OER initiatives, including adapting existing OER publishing models, navigating institutional culture, moving OER programs beyond affordability, and sustaining and scale OER programs with shifting institutional support[37].
Luo et al., 2020	The purpose of this review is to explore strategies for OER adoption that promote efficient and practical design.	This survey was collecting from 51 accessible educational materials and research made in nations all around continents.	This extensive review of studies looks at the evidential phenomena that are prominent in today's world study.	This research identified that accessibility, stability, and recreating. There are enormous challenges that prevent OER from undermining modern textbook designs;there are no significant

				different types of learning performance when educators introduce OER. The introduction of OER as teaching methods is complicated but can successfully promote successful learning when adequately implemented[38].
X. Zhang et al., 2020	This study presents a systematic review based on published papers related to OER and OEP for learning accessibility, significantly disabled students.	Systematically reviewed 31 papers.	This study presents a systematic review based on published 31 research papers. Based on the review of the 31 identified studies, 1616 papers conducted assessments to evaluate the accessibility of OER.	Nine countries have led research about OER and OEP for accessible learning to disabled students. Ecuador had 11 papers, Spain, with six articles, UK-4, Greece-3, Ireland-2, Turkey, Uruguay, Tunisia, Italy-1[39].
Todorinova & Wilkinson, 2020	The survey collected faculty's perceptions about the award program, experiences with OER, and interest in open textbook authoring.	This survey assessed the experiences of 56 faculty who received OAT awards in a textbook affordability program at Rutgers University.	The survey questions directly asked about the course materials used in redesigned OAT courses, the financial incentive award offered, and the new course materials' impact on students. It is demographic questions.	Responses suggest that the program is well received and that funds are adequate for adopting new course materials. However, they also indicate that even participating faculty varies significantly in their knowledge and use of OER and their interest in authoring open textbooks[40].
Schellinger & Coghill, 2020	This article will examine the use of OERs to help reduce the cost of attendance for medical and nursing school.	Review based on published papers.	Review based on published papers	Librarians can be agents of change. Top-level administrators, including chancellors, presidents, provosts, vice-chancellors, and deans, can also help facilitate change. Librarians

				dsould look outside of their buildings to find partnerships wherever they can to bring OER to their respective institutions[41]
Lee, 2020	Who opens online distance education, to whom, and for what?	The above search, conducted in August 2019, returned 137 items, and 29 papers were selected.	The search was conducted based on the title, abstract, and keywords of articles, using the following search terms: "open education," "university," "higher education," "online education," "online learning," "distance education," "distance learning." It analyzed the selected papers using a grounded theory approach.	The results show that despite the growing importance of the social mission to make Education for All among diverse actors, a clear understanding of the actual process of OEP in real-life higher education settings and clarity on how those actors serve disadvantaged learners are lacking[42].
Pitt et al., 2020	It was supporting open educational practices through free textbooks. It focussed on awareness of available educational resources.	Survey research with United Kingdom educators. Over 4000 UK educators were invited via email to participate during September 2018.	The survey was divided into two sections and comprised 25 questions. The first part of the study focuses on demographic questions—the second half of the study focussed on textbook use and rationale.	The findings indicate strategies for supporting pedagogical innovation and student access through the mainstream adoption of open textbooks[43].
Wang et al., 2021	The current study aims to increase knowledge of factors influencing Digital Educational Resourc-	The sample size is 709 rural teachers. The participants were teachers in primary and secondary scho-	A sampling method to collect data with an online survey. Data analysis: exploratory factor analyses (EFA) using IBM SPSS 25	The study found that both internal motivation and external motivation significantly influenced attitudes and sharing behaviour within or outside sch-

	es-sharing behaviour among rural school teachers.	ols in rural areas in southwest China.	and dispositional variables, confirmatory factor analyses (CFA) using Mplus 8.3. And then using Cronbach's alpha method.	ool. However, internal motivation positively influences, whereas external stimulation negatively impacted both perspective and sharing behaviour. Future research should focus on teachers' sharing behaviour on different online sharing platforms[16].
Zou et al., 2021	This study examines the relationship between social presence and learners' prestige in a MOOC learner network.	The sample size is 456 students registered in Data Visualization for Storytelling and Discovery in Journalism, a professional development MOOC designed and managed by a large research university in the Southern United States.	This MOOC consists of four modules. There are learning materials in each module, such as readings, instructional videos, quizzes, and a discussion forum. Students were encouraged to participate in the forum by the end of each module to discuss specific questions regarding the module's topic and reflect on the concepts and techniques they have learned.	The findings will inform MOOC learners how to strategically present themselves in the discussion forums to increase peer interaction possibilities and achieve productive learning outcomes. Further studies are needed to investigate the impact of social presence using datasets from MOOCs of other topics to test our findings' reliability and validity[44].

According to this related literature review, the researcher finds the current research gap is open educational practices. Particularly, open educational practices for research scholars are a minimum number of articles only available (see Table 1). Then the researcher chooses the current research gap as “usage and performance of open educational resources among research scholars from the state universities of Tamilnadu research scholars in education.”

6. Methodology

The target group was a research scholar in the state universities of Tamil Nadu. State Universities of Tamil Nadu research scholars selected with the random sampling technic. University grant commission was categorized as some universities are under the state universities of Tamil Nadu in India. Presently, 22 universities are under the state universities of Tamil Nadu in India. In the state universities of Tamil Nadu, approximately 12,000 research scholars in the current academic year. As used random sampling technic and choose 300 research scholars in education were randomly selected from the st-

ate universities of Tamil Nadu to complete a printed survey between 17/10/2020 to 26/12/2020. Simultaneously, the survey conducts through the website, so any student interested could also meet the same questionnaire's online version. Hence, the final number of completion included both printed hard copy and soft copy surveys. The investigator and Guide develop the tool for using open educational resources and performance in education scales.

7. Analysis of Data

Table 2. Level of usage of open educational resources of state universities of Tamilnadu research scholars.

Low		Moderate		High	
N	%	N	%	N	%
115	38.3	95	31.7	90	30

Table 2 shows that 30 % of the students have a high level of open educational resource usage.

Table 3. Level of performance in education of state universities of Tamilnadu research scholars.

Low		Moderate		High	
N	%	N	%	N	%
122	40.7	106	35.3	72	24

Table 3 shows that 24 % of the students have a high-level performance in education.

Hypothesis (H0): 1

There is no significant difference between male and female state universities of Tamilnadu research scholars regarding the usage of open educational resources.

Table 4. The Significant difference between male and female state universities of Tamilnadu research scholars in their usage of open educational resources.

Gender	N	Mean	SD	t-value
Male	127	68.191	9.5642	3.9696
Female	173	62.904	12.602	

Table 4, the calculated t-value of 3.969, is greater than the table value at 0.05 level. Hence, there is a significant difference between male and female research scholars in using open educational resources.

Hypothesis (H0): 2

There is no significant difference between male and female state universities of Tamilnadu research scholars regarding the performance in education.

Table 5. The significant difference between male and female state universities of Tamilnadu research scholars in their performance in education.

Gender	N	Mean	SD	t-value
Male	127	57.501	14.565	2.5556
Female	173	52.703	17.103	

Table 5.the calculated t-value of 2.555 is greater than the table value at the 0.05 level. Hence, there is a significant difference between male and female state universities of Tamilnadu research scholars in their educational performance..

Hypothesis (H0): 3

There is no significant relationship between usage of open educational resources and performance in education among state universities of Tamilnadu research scholars.

Table 6. The significant relationship between usage of open educational resources and performance in education among state universities of Tamilnadu research scholars.

Variables	Calculated r- Value
Usage of open educational resources	0.0381
Performance in education	

Table 6. The calculated r-value is less than the table value; there is no significant relationship between usage of open educational resources and performance in education of state universities of Tamilnadu research scholars.

8. Findings and Implementing Areas of Open Educational Resources (OER)

There is a significant difference between male and female state universities of Tamilnadu research scholars in their open educational resources. There is a significant difference between male and female research scholars in their performance in education. There is no significant relationship between open educational resources and performance in education among state universities of Tamilnadu research scholars.

OEP is spread worldwide as practices in the research field for supporting researchers. It has enormous use in the research field in terms of reuse, copy-right use, etc. In India, OER and OEP are not introduced so much in the educational area, but they will spread in our country for the next ten years. As OER product or use, we had MOOC, NPTEL courses in recent time as free education [45]–[48]. In India's future, OER is going to widespread as a free education tool as it is. OER and OEP have an indirect effect on GDP in terms of free human resources and educational tools. In pandemic situations (like lock-down due to COVID-19) [49]–[51], OER is useful among learners because, in this time, without coming to the institution, learners can learn from their remote location. Open educational practices also help the researcher, academician, teacher for the research activity purpose in this pandemic situation. OER and OEP are implemented in the human resource sector to develop the educational goal [52]–[55]. OER provides free resources to the education field and readers like open-source resources for learning, and it has wider use in the education field. This COVID-19 virus infection is having the most significant impact nationwide. Significantly more than 91 percent of students have lost their fundamental rights to education due to the closure of many educational institutions [49]–[51], [56]–[59].

There are many lessons that human society has learned during this time. We know the importance of distance education and the importance of open education resources that provide the essential resources. Therefore, we compelling to make the most significant change in the education system of the future. People are in great fear because this corona virus [45], [60], [61] can kill elderly children and the sick. Parents, in particular, are having trouble sending their children to school. Therefore all educational institutions need to improve technology, open educational resources, and infrastructure. Even in such a situation where the disease spread is rare, students continue to receive their learning process with free educational resources. And this "OER" is the standard solution for any disasters (virus outbreak, world war, flood, rain, recession, famine, storm, etc.) that affect students' education. Education should be free, and OER mainly supports as well as promote that thought..

9. Conclusion and Recommendations

Over the past few years, OER has grown exponentially to meet its needs. This development is an essential need of the twenty-first century. In the improvement of education quality, OER brings to make the education digitalized with modern-day technology. In the present time, OER is widely using in institutions for upgrading the era of the pen-notebook period to the digital study era in the context of making the availability of education cum resources anytime, anywhere, to any person. Education should be free, and OER mainly supports as well as promote that thought. OER is helping to adapt to study in all situations. The COVID-19 epidemic and paralysis have questioned the education of migrant workers and their children. Open educational resources (OER) and open educational practices (OEP) are a sustainable and easy education system in the future, even in a virus outbreak, storm, flood, and world war. These free and readily available open education resources give students confidence and freedom of learning. Research scholars must be encouraged to do mini projects on the influence of open educational resources in day-to-day life. Research supervisors should encourage and direct to using the open educational resources to enhance the research scholar's education performance.

10. Acknowledgments

The authors would like to thank the state universities of Tamil Nadu, India, research scholars for their participation in the study. Express appreciation to that all authors whose references we utilized in this research work.

Competing interests

The authors have no conflict of interest to declare.

Contributions

Each author contributed evenly to this paper. All authors read and approved the final manuscript.

Acknowledgements

The authors would like to thank the state universities of Tamil Nadu, India, research scholars for their participation in the study. Express appreciation to that all authors whose references we utilized in this research work.

Availability of Data and Materials

The datasets generated and analyzed during the current study are not publicly available due to privacy reasons but are available from the corresponding author on reasonable request.

Energy Harvesting is a method by which the energy is captured and stored so that it can be conditioned and used later. For energy harvesting many devices like electrostatic, piezoelectric and electromagnetic transducers are used. The output from transducers in the range of millivolt is to be rectified, boosted and regulated. So a new boost rectifier topology is designed for energy harvesting applications. This rectifier integrates both boost and buck-boost converters for conditioning the output. The rectifier is designed for an input voltage of 12 V (RMS) AC and an output voltage of 30 V (DC).

Keywords: Energy harvesting, boost rectifier, boost converter, buck boost converter, AC/DC conversion, bridgeless topology.

1. Introduction

Energy harvesting means it is a process of capturing and converting energy from sources like vibrations, piezoelectric devices, solar power, thermal energy, wind energy, salinity gradients, kinetic energy etc. into electrical energy. This energy is conditioned either for direct use or accumulated and stored for small wireless autonomous devices like wireless sensors, walkie talkie etc. This provides an alternative source of power for applications in locations where there is no grid power. The harvested energy is low and it cannot be used to power a device.

Most of the low-power electronics devices like remote sensors etc. are powered using batteries. However, these batteries must be replaced after few years. The replacements will be costly if there are a number of sensors in remote locations. Most energy harvesting applications are designed to be self-sustaining, cost effective and require only little servicing.

Fig 1- Block Diagram of Energy Harvesting system

In energy harvesting systems, power electronic devices are the key interface between transducer and electronic load. In certain vibration powered electrical generators, AC is produced which is to be converted to DC to feed the electronic load. These power conditioners regulate the power delivered to the load. Since the energy harvesting circuits provide an output of few millivolts, this is needed to be rectified and boosted in order to deliver it to the electronic load.

Conventional AC/DC converters mainly consist of two stages: A diode bridge rectifier and a DC-DC converter which regulates the rectified AC voltage. The voltage drop produced by the diode bridge rectifier due to the conduction of diodes is considerably high when it is used for low voltage applications. Later instead of Silicon diodes, CMOS diodes with low voltage drops were used. But these diodes also had drawbacks. In certain converters transformers were used to boost the voltage. However the size of transformer required for low frequency range is large. The new approach in the energy harvesting system is to use AC-DC bridgeless converters. Here the boost converter topology and buck converter topology is integrated to form bridgeless boost rectifier. The boost converter is a commonly used power conditioning circuit with simple circuit, voltage step-up capability, and high efficiency. The buck-boost converter has an ability to step up the input voltage with a reverse polarity and it would be useful to condition negative half-cycle. Here, both the converter topologies uses a common inductor and capacitor. Bridgeless boost converter consists of two switches S1 and S2, two diodes D1 and D2, one inductor L and capacitor C.

2. Modes of Operation

When the input voltage is positive, the circuit operates in boost mode. When the input is negative, the circuit operates in buck boost mode. The circuit operates in Discontinuous Conduction Mode (DCM). There are six modes of operation for the converter. During modes 1 to 3 the circuit operates in boost mode and during modes 4 to 6 the circuit operates in buck boost mode.

Fig.2-Modes of Operation

1. **Mode 1:** The switch S2 is turned ON at t_0 . The inductor current is zero at that time. The turn on is achieved through Zero Current Switching scheme (ZCS). Since S1 and S2 are conducting, inductor L is energised by the input voltage. Both diodes are reverse biased. The load is powered by the energy stored in the output filter capacitor C.
2. **Mode 2:** S2 is turned OFF at t_1 , where $t_1 - t_0 = d_1 T_s$, d_1 is the duty cycle of the boost operation, and T_s is the switching period. The energy stored in the inductor during Mode I is transferred to the load. The inductor current decreases linearly. During this mode, switching loss occurs during the turn on of diode D2.

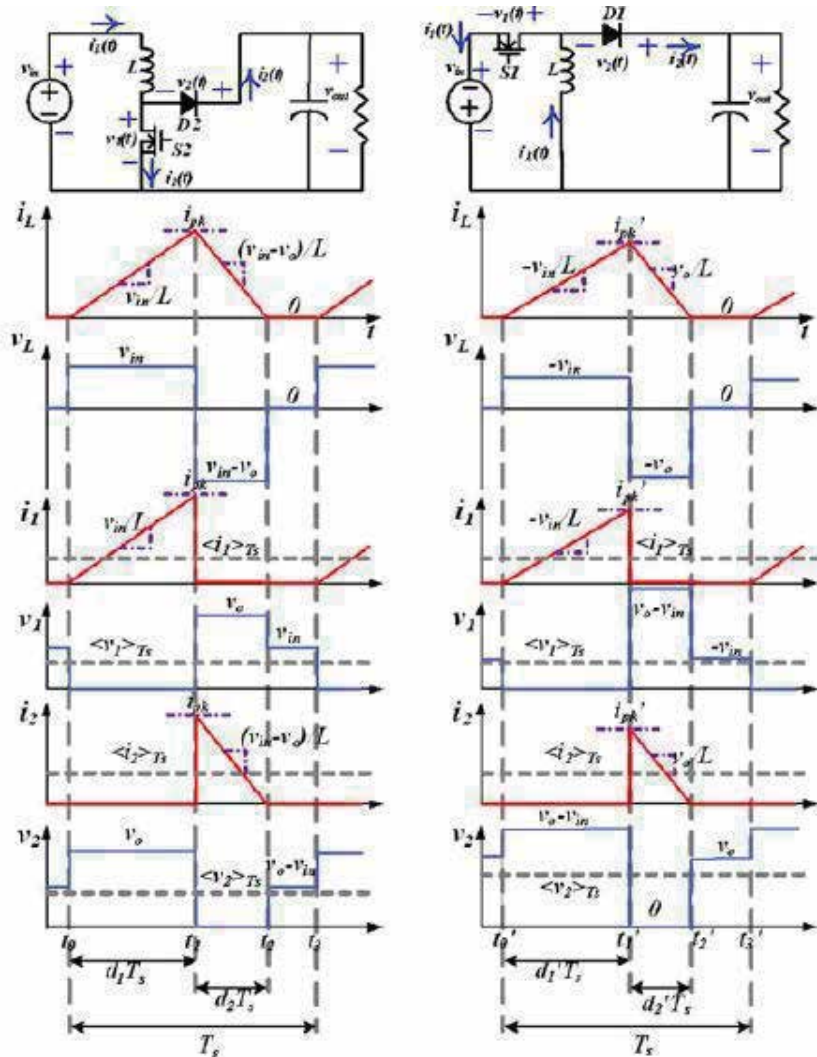

Fig.3 -Typical waveforms of Rectifier

3. **Mode 3:** D2 is automatically turned OFF as soon as the inductor current becomes zero at t_2 ($t_2 - t_1 = d_2T_s$). This avoids the reverse recovery loss of diode. The load is again powered by the stored energy in the capacitor. The converter would return to Mode I as soon as S2 is turned ON, if the input voltage is still in positive cycle.

4. **Mode 4:** During the negative input cycle, Mode IV starts as soon as S1 turned ON at t_0' . ZCS condition can also be achieved by ensuring the converter operation in DCM. The energy is transferred to the inductor L again, while the output filter capacitor C feeds the load

5. **Mode 5:** At t_1' , S1 is turned OFF, where $t_1' - t_0' = d_1T_s$, d_1 is the duty cycle of the buck-boost operation. The energy stored in the inductor during Mode IV is transferred to the load. The inductor current decreases linearly. During this mode, switching loss occurs during the turn on of the diode D1..

6. **Mode 6:** When the inductor current decreases to zero at t_2' ($t_2' - t_1' = d_2'T_s$), D1 is turned OFF at zero current. The load is continuously powered by the charge stored in the output capacitor. The converter would return to Mode IV as soon as S1 is turned ON, if the input voltage is still negative.

3. Simulation Results

The boost rectifier is designed as a scaled up version of the power electronic interface which is actually used in energy harvesting applications. The boost rectifier works at an input voltage of 12 V (RMS) AC and at an output voltage of 25 V DC. The performance of the converter was first tested and evaluated by using the software MATLAB/Simulink version 2015a. The sampling used is discrete and the toolboxes used are Simscape and Sim-power system. A sampling time of $0.1 \mu s$ was given.

Table 1- System Specifications

Sl. No	System Parameters	Specifications
1.	Input Voltage	12 V (RMS) AC
2.	Output Voltage	25 V DC
3.	Switching Frequency	20 kHz
4.	Inductor	26 μ H
5.	Capacitor	1000 μ F
6.	Duty ratio 1	0.8
7.	Duty ratio 2	0.2

Fig. 4- Gate Pulse to S1

Fig 5-Gate Pulse to S2

Fig 6- Output Voltage Waveform

4. Comparison with Conventional Energy Harvesting Systems

The boost rectifier and conventional energy harvesting system was simulated with the same constraints. The settling time of output voltage is more for conventional system when compared to that of bridgeless boost rectifier. Also the boosting action for the conventional system is less. Moreover the boost rectifier produces higher voltage than the conventional system because of its duty ratio. By using duty ratio the output voltage of the boost rectifier can be controlled whereas the output voltage of the conventional system cannot be controlled. Fig.7 and fig.8 shows the comparative analysis.

Fig.7-Output voltage of bridgeless boost rectifier

Fig.8-Output voltage of conventional energy harvesting system

5. Conclusion

The rectifier integrates both boost and buck-boost converters. In the positive half cycle, the circuit acts as a boost converter and in the negative half cycle the circuit acts as a buck-boost converter. The circuit is operated in discontinuous conduction mode (DCM) so that the switching losses can be reduced and control circuitry for DCM is simple. The conversion efficiency is more when compared to that of conventional rectifiers. Conduction losses are less. The disadvantage is that the rectifier has switching losses. When compared to the conventional energy harvesting systems this rectifier shows better performance in boosting the output obtained from harvesters. This type of rectifier can be used in resonant circuits, medical fields, communication devices used in remote areas etc.

A b s t r a c t

Telemedicine generally means the use of Telecommunication and Information Technology is for delivering medicinal care to the patients. Telemedicine concept was initiated from around thirty years back. At the time of inception use of telephone, slow scan images are the tools used to enable the technology. The term Telemedicine refers the utilization of telecommunication Technology for medical Diagnosis, treatment and patient care. By using Satellite Technology and video Conferencing equipment to conduct a real- time consultation between two different countries medical specialists, this technology may be simple for health professionals during the Pandemic Situation.

Keywords: Digital Resources; Information Technology; Pandemic Situation; Telemedicine; Telecommunication.

1. Introduction

Today the Digital Resources and Information Technology plays a vital role in the field of teaching, research and learning process. It is assumed that the Arts and science students feel more dependent on the Internet and Telecommunication service for their class assignments and for the latest Information of their subject areas. During the pandemic situation. In these days College Teachers also use Digital Resources to updating their knowledge and online class room teaching is similarly same as the Telemedicine Technology. Most of the activities are same in online Teaching and Telemedicine Technology. Even though the telemedicine concept is in practice some years ago, enough awareness of that is not reached to all. In the pandemic situation fear of the disease spread and not enough transportation, people try to fulfill their medical needs even sitting at their home. At that time they have contacted the medical professionals through various electronic devices and fulfilled their medical requirements. By this method the common people entered the first step in the concept of telemedicine. This study deals with that experience elaborately based on a survey given to Faculty members and Post Graduate students of Malankara Catholic College Mariagiri.

2. About Malankara Catholic College, Mariagiri

Malankara Catholic College is owned and managed by the Diocese of Marthandam with the approval of the Government of Tamil Nadu, and is affiliated to Manonmaniam Sundaranar University, Thirunelveli.

The college was born out of the Educational Vision of the Most.Rev.Lawrence Mar Ephraem, the first Bishop of the Catholic Diocese of Marthandam, established on 20th July, 1998. Subsequent to his eternity on 8th April, 1997, the Most.Rev.Yoohanon Mar Chrysostom became the second Bishop of the Diocese of Marthandam on 1st July, 1998. Under his untiring inspiration coupled with the foresighted efforts of Rev.Fr.Prem Kumar, M.S.W, the previous Correspondent/Secretary; the polite behavior of Rev.Fr.Maria Arputham M.A, the former Bursar, the able guidance of the former Principals and the dedicated staff members, the college began to flourish. At present, the college stands as a land mark in the field of higher Education with the new dynamic Chairman and Manager, His Excellency the Most.Rev.Dr.Vincent Mar Paulos, the Bishop of Marthandam Diocese; an Eminent Correspondent/Secretary Rev.Fr.Jose Bright and an experienced Principal, Dr.J.Thampi Thanka Kumaran M.Sc(IITM)Ph.D. (University of Hyderabad).

In this institution 12 UG courses, 11 PG courses, 4 M. Phil Research wing, and 5 P.hD research wing are functioning.

2.1. Vision and Mission of the College

Vision : Transformation of Society through Human Resources.

Mission : Excellence in value based Education and Research for the development of human Resources.

Motto : "Learn to Serve"

Goals : To impart quality education through an innovative learning environment.

3. Literature Review

This word 'Telemedicine' is derived from the Greek and Latin Origin in a mixture of two words, 'tele and mederi', which means 'at a distance' and 'healing' respectively. Telemedicine has several definitions, mainly physicians examine patients at distance through the use of telecommunication technologies to deliver health care. (1)

In its earliest age smoke signals used by African villages to warn people in case of serious disease, to stay away from the village. People living in remote areas of Australia, in early 1990s used two-way radios to communicate with the Royal Flying Doctor Service of Australia.(2)

4. Objectives

Usage of Digital Resources and Information Technology through Telemedicine System are the main purposes to this study. The main objectives are:

- To identify the personal clinical visit during pandemic situation.
- To identify the easiest way to consult the medical professionals of various places and get diagnosis at the same time which enables low cost.
- To identify various purposes to chat/teleconferencing to medical professionals.
- To identify needed digital /electronic resources /technological devices to use telemedicine facility.
- To identify present and future usages of telemedicine facility.
- To identify impact of telemedicine facility.

5. Scope

Advanced studies of various countries may be used to all countries, in the field of medicine necessities of various Infrastructure buildings are lessened. Professionals of Electronics and Telecommunication field may get opportunities in the field of medicine.

The involvement of Electronics Digital resources and Telecommunication paves the way to increases the Research and Development of Telemedicine in future.

6. Types of Telemedicine

6.1. Store and forward Telemedicine

In this system medical data's like medical images, bio signals etc. are collected and then transmitting this data to a medical specialist at a convenient time. The presence of both the parties at the same time is not at the same time is not at all required. Dermatology, radiology and pathology are common specialties to asynchronous Telemedicine. A component of this transfer is a properly structured medical record preferably in electronic form.

6.2. Remote monitoring

This enables medical professionals to monitor a patient using various technological devices, remotely also known as self-monitoring or testing. Chronic disease such Heart Disease, Diabetes Mellitus, or asthma are primarily used for managing, by this method. This monitoring service may be cost effective but can provide comparable Health outcomes and supply greater satisfaction to patients.

6.3. Interactive telemedicine

This services provide interaction between the patient and the professionals. Which includes phone conversation and online communication, many activities and assessments can be conducted comparably in face to face visits, such as History review, physical Examination and psychiatric evaluations. This Telemedicine services is less costly them in-person clinical visit.

7. Working System Of Telemedicine

The Telemedicine application consists of mainly 3 components.

7.1. The Central Control Unit:

The central control unit is the nerve center of the telemedicine application. Generally sited at a large

tertiary hospital, it is manned 24 hours a day days a week, is fully IT enabled and capable of the following:

- * Replies by specialists to queries based on Electronic Medical Records (EMR) of patents, transmitted to them from the periphery.
- * Opinions on ECGs, EEGs, CATs, MRIs, X-Rays, Ultrasounds, image of pathological specimens, histological slides, skin, ear, nose, throat, eyes, fundus, etc transmitted digitally.
- * Live chat with Medical Professional on patient care.
- * Teleconferencing between patient to Medical Professional and Medical Professional to specialist.
- * Remotely monitored surgical procedures.
- * Monitoring chronic cases.
- * Counseling of selected psychiatric cases.

7.2. The Communication Link:

Depending upon various factors , communication between the central and peripheral units could be by telephone lines (analog, ISDN),mobile phones, satellite phones, fiber–optic cables ,wireless LANs, Satellite links,WiFi,WiMAX,4G etc.

7.3. The Peripheral unit:

This is the actual workhorse of the telemedicine application. Depending on requirements there could be anywhere from 50 to 500 (or more) of such units spread over a geographic location in consonance with the aims and objectives of the telemedicine system. A single unit would consist of a computer terminal (or a LAN) in communication (or capable of being in communication) round the clock with the central control unit. The software on this terminal (or LAN) would be capable of capturing and digitizing ECGs, EEGs, CATs, MRIs, X-Rays, Ultrasounds, images of pathological specimens, histological slides, skin ear, nose throat, eyes etc. All of these images along with the patient data in the form of an electronic medical record would be stored and /or transmitted, if necessary in real time, to the central control unit for necessary feedback. It would also be live chat and teleconference capable (3).

8. Telemedicine in Village Resource Centre

ISRO has also initiated pilot projects for integrating Telemedicine /Tele-health with the Resource Information database as well as Tele – Education Facilities at the village Resource Centre /Community Centre (VRC) to reach out to more rural areas of the country. The first of the pilot projects has been implemented in the state of Tamil Nadu wherein the nodal center operated by an NGO agency is connected to remote villages in three districts and more are to come in the future. One of the major advantages of Telemedicine technology has been the saving of cost and effort to the rural patients as they are not required to travel long distances for obtaining consultation.(4)

9. Vision of Dr.A.P.J.Abdul Kalam about Telemedicine

Dr.A.P.J.Abdul Kalam says that construct an internationalized quality hospital at Kudankulam with 500 beds and provide telemedicine facility for all villages. (5)

10. Significant Benefits and Healthcare & Uses of Telemedicine System

* For Those people living in isolated communities and remote regions The Telemedicine is extremely Beneficial and is currently being applied in virtually all medical domains. Patients live in Isolated and remote areas can get medical facilities by a professional specialist who can provide complete and accurate examination. And also the patient may not have to travel, irrespective of distance or time

* Experienced medical professional at a distance place can show and instruct medical e the patient need not wait, to get the medical facilities. Staff in another location through this system, more effectively, by which is used as a teaching tool.

* It increases efficiency through better management of chronic deceases and it reduces travel times, also reduces cost of Healthcare.

* This Tele monitoring program include subjective questioning of patients Health and Comfort, in addition. This system can keep the patient in touch with the medical professional, who can question the patient over phone or monitoring software. By which the professional can make decision about the patient based on subjective and objective information.

* Uses of Tele monitoring devices include Blood pressure, Blood glucose, Heart rate, Hemoglobin etc. By the Tele monitoring system the patient has necessary monitoring about and vital sign, is capable of providing Information.

* The professional may check these statistics and determine the best course of treatment, on the severity of the patient's condition.

11. Methodology

The investigator personally visited to collect data from the respondents. The questionnaires for the users of telemedicine were filled up by the Faculty and Post Graduate students of Arts and Science College. A total sample of 25 Faculty members and 25 Post Graduate Arts and Science Students was taken up for the present study.

For sampling, random sampling process was followed for data collection. The sample was random in the sense that the faculty and post Graduate students were randomly selected from various PG departments in Malankara Catholic College Mariagiri. Taking at least five Faculty members and five Post Graduate students were selected randomly from each Departments such as Biotechnology, Biochemistry, Microbiology, Geology & Chemistry. 50 questionnaires were distributed among the Faculty and Post Graduate Arts and Science Students of the Malankara Catholic College. Under this study all questionnaires were received back duly filled in.

12. Analysis

Table 1. Frequency of regular hospital visit before pandemic situation

Hospital visit before Pandemic Situation	Frequency	Percentage (%)
Daily	2	6
Once in a week	8	16
Once in a month	15	30
Once in a year	25	50
Total	50	100

Note: n=50

The question was asked to find out the frequency with which respondents visit the hospital before pandemic situation. A total of 2(4%) indicated that they visit the hospital for their health before pandemic situation every-day, 8(16%) of them reported that they visit once in a week, 25(50%) visit it once in a month, while 15(30%) respondents reported that they visit the Hospital once in a year. This indicates that most of them visit the Hospital at least once in a month regularly.

Figure 1. Frequency of regular Hospital visit before pandemic situation

Table 2. Amount of time spent on the hospital visit

Amount of time	Frequency	Percentage (%)
7-9 hours	6	12
5-6 hours	9	18
2-4 hours	14	28
Less than one hour	21	42
Total	50	100

Note: n=50

Table 2 shows that the maximum number of respondents of 21(42%) spent the amount of time for their regular hospital visit is less than one hour, 14(28%) spent the time for their hospital visit 2- 4 hours, 9(18%) spent the time for their hospital visit 5-6 hours, only 6(12%) respondents have indicated that they spent the amount of time for their hospital visit 7-9 hours.

Figure 2. Amount of time spent on the Hospital Visit

Table 3. Distance to the location of the hospital used

Distance to the location	Frequency	Percentage (%)
Within 1km	5	10
Within 5km	7	14
Within 25km	20	40
Within 50km	15	30
Above 50km	3	6
Total	50	100

Note: n=50

Table 3 shows that only 3(6%) respondents use the hospital location above 50km, 5(10%) within 10km, 7(14%) within 5km, 15(30%) of respondents used the hospital location within 50 km, and the majority of the respondents of 20(40%) used the hospital location within 25 km.

Figure 3. Distance to the location of the hospital used Frequency

Table 4. Reason to visit hospital

Reason to visit hospital	Frequency	Percentage (%)
For self	18	36
For their parents	14	28
For their siblings	5	10
For their children	13	26
Total	50	100

Note: n=50

Respondents were asked to indicate the reason to visit hospital .It is found that most of the respondents of 18(36%) visit the hospital for self. A total of 14 of them (28%) indicated that they visit the hospital for their parents, 13(26%) of respondents visit the hospital for their children and 5(10%) of them for their siblings.

Figure 4. Reason to visit hospital

Table 5. Types of health problems for visit hospital

Types of health problems	Frequency	Percentage (%)
For common illness (fever, headache etc.)	15	30
For Diabetic mellitus	5	10
For Obesity	3	6
For Respiratory diseases	9	18
For Ophthalmic diseases	10	20
For ENT diseases	8	16
Total	50	100

Note n=50.

Another question was related to the types of health problems for hospital visit. Table 5 shows that among the health problems most of the respondents 15(30%) visit the hospital for common illness (fever, headache etc...), 10(20%) of respondents visit the hospital for ophthalmic diseases. Hospital visit for Respiratory related disease comes next, this is being for hospital visit by 9(18%) respondents. Next in order come for ENT disease with 8(16%) respondents. For diabetic mellitus with 5(10%) respondents and for Obesity with 3(6%) respondents.

Figure 5. Types of health problems for visit hospital

Table 6. Ways to get medical advises in the pandemic situation.

Ways to get medical advises	Frequency	Percentage (%)
Guidance from their regular consulting medical professional	10	20
Advice of medical professional in television	13	26
Message from social medias	16	32
Articles in news paper	7	14
From healthcare magazines	4	8
Total	50	100

Note n=50

Table 6 says that ways to get medical advices in the pandemic situation is various types. The ways to get medical advices in the pandemic situation mainly come from 5 types. 16(32%) of respondents get medical advices from social media. 13(26%) of respondents are get the advice of medical from television shows. 10(20%) of respondents get guidance from their regular consulting medical professional which takes a minimum of slot time to get their needed information. Another 7(14%) of respondents report that they get the needed medical information from newspaper articles and the respondents of 4(8%) only get the medical information from health care magazines.

Figure 6. Ways to get medical advises in the pandemic situation

Table 7. Types of medium used by the respondents to communicate their regular consulting medical professionals in pandemic situation.

Types of medium used	Frequency	Percentage (%)
Through audio call	20	40
Through video call	15	30
Through Email	5	10
Through chat with messages	10	20
Total	50	100

Note n=50

Table 7 exhibit that a majority of the respondents of 20(40%) communicate to their regular consulting medical professional through audio call. 15(30%) of respondents communicate to their medical professionals through video call. 10(20%) of respondents through chat with messages and only 5(10%) of respondents communicate to their medical professionals through email.

Figure 7. Types of medium used by the respondents to communicate their regular consulting medical professionals in pandemic situation

Table 8. Medium used to send medical reports to their regular consulting medical professionals in pandemic situation

Medium used	Frequency	Percentage (%)
Through Email	17	34
Through WhatsApp	33	66
Total	50	100

Note n=50

Table 8 shows that most of the respondents 33(66%) use to send medical reports to their regular consulting medical professionals in pandemic situation through WhatsApp and the remaining 17(34%) of respondents were used to send through Email.

Table 9. Problems faced while contacting the medical professional through electronic devices.

Problems	Frequency	Percentage (%)
Network related problems	20	60
Electronic device related problem	30	40
Total	50	100

Note n=50

Table 9 shows that most of the respondents 30(60%) faced the problem while contacting the medical professional through electronic devices is network related problems. Another 20(40%) of respondents faced electronic device related problem while contacting medical professional

Table 10. Satisfaction of consultation to the medical professional through electronic media

Satisfaction of consultation	Frequency	Percentage (%)
Fully	13	26
Partially	17	34
Least Satisfied	20	40
Total	50	100

Note n=50

Table 10 shows that most of the respondents of 20(40%) least satisfied their consultation through electronic media. 17(34%) of respondents partially satisfied and the remaining 13(26%) of respondents only fully satisfied for their medical consultation through electronic media

Figure 10. Satisfaction of consultation to the medical professional through electronic media

13. Suggestions

Based on the survey findings of the study, the following suggestions are put forward to improve the use of Telemedicine system for common people.

* In this telemedicine system transportation expense, traveling huddles and Hospital expanse are very much less, but in the areas where are remote and low network coverage, this system can't be implemented effectively. And hence there should not be any area which is not covered by the network, then only everybody have its use.

* Moreover the users of this Telemedicine system must have at least some knowledge in the electronic devices to handle. Also the hospitals must conduct seminars to make awareness at least to their regular consulting patients, how to contact the medical professionals and fulfill their needs, at those times when they can't come to the hospitals directly during the pandemic situation.

14. Conclusion

This Telemedicine system is in Voyage, in one form or another, for over thirty years. In short a nurse or medical professional providing medicinal advice over telephone is Telemedicine system. The recent activity on Telemedicine Application employ advanced image as well as audio capabilities. This Telemedicine Technology now range to sophisticated integrative Teleconferencing system. In this Telemedicine system special interests in these Advanced Technology is increasing Significant about Telemedicine remains same. This Telemedicine system plays a vital role during the pandemic situation, and this became an unavoidable medicinal Technology in future also.

15. Acknowledgements

The author express her sincere thanks to the Malankara Catholic College Management for their kind cooperation and permission to collect the data from staff, and students. Then the authors thanks to the staff, and students those who took the time to participate in the survey.

r
a
c
t**

The purpose of the study was to find out the effect of yogic training on selected strength variables among college men basketball players. Thirty subjects were selected from Sourashtra College. The subject's age ranged from 18 to 24 years. The selected subjects were divided into two groups with fifteen subjects in each group selected randomly yogic training group and control group. The training periods of yogic training group were six weeks, five days per week. Control group did not undergo any training programme other than their routine work. To find out the significance difference between the means on the criterion variables correlated 't' ratio was applied. Pertaining to present study it processed with appropriate statistical technique. The obtained 't' values are tested at 0.05 levels.

Keywords: 1. Yogic Training, 2. Leg Strength, 3. Arm Strength and 4. Explosive Strength.

Introduction

Physical training entails exposing the organism to a training load or work stress of sufficient intensity, duration and frequency to produce a noticeable or measurable training effect, that is, to improve the functions for which one is training. To achieve such a training effect, it is necessary to expose the organism to an overload that is larger than the one regularly encountered during everyday life. It is a common conception in training environments that "to build up, one must first break down." Admittedly, exposure to the training stress is associated with some catabolic processes, such as break down of glycogen, followed by an overshoot or anabolic response that causes an increased deposition of the molecules that were mobilized or broken down during training. As to the effect on other cellular components, this is the best an imprecise statement.

Basketball

There, physical educator Luther Gulick asked him to invent a new indoor game, which could be played during the cold winter. He also made it for a physical education class to play. He started work on it in December 1891. He wrote that he took some ideas from other sports: when he was young, he played with his friends a game called "Duck on a Rock." In this game, one boy guarded his "duck" from the stones of the others; and the fun began as the boys gathered their stray shots. It was this game that was later to play such an important part in the origin of basketball. The first game was played on December 29, 1891.

Yoga

Yoga means to “yoke” to “unite” to bind to “link” to connect or to “merge”. As yoke joins two bulls together, the yoga unites body and mind together. The merger of soul with God, and the experience of oneness with him is yoga. It is possible only through the control over sense organs and through continued practice and detachment. According to the great Sage Patanjali’s the withdrawal of sense organs from their worldly objects and their control is yoga.

Methodology

The purpose of the study was to find out the effect of yogic training on selected strength variables among college men basketball players. Thirty players were selected at random as subjects from Sourashtra College, Madurai. The subject’s age ranged from 18 to 24 years. The selected subjects were divided into two groups with fifteen subjects in each group selected randomly yogic training and control group. The training periods of experimental group were six weeks, five days per week. Control group did not undergo any training programme other than their routine work. The pre and post tests were administrated for all the groups before and after the experimental treatment.

Selection of Tests

The selected criterion variables were concerned the leg strength, arm strength and explosive strength were tested and measured by 25 meters hopping (in seconds), dip strength (in seconds), vertical jump (in centimeters).

Statistical Technique

To test the significance of ‘t’ values as level of significance 0.05 level was chosen for the required table value for the degrees of freedom. The data collected prior to and after the training period on leg strength, arm strength and explosive strength for the experimental group have been analyzed.

Results

Leg Strength

The results of the dependent ‘t’-test on the data obtained for leg strength of the subjects in the pre-test and post-test of the yogic training group and control group have been analyzed and presented in Table 1.

Table – 1
Summary of mean, standard deviation and dependent’s’ test for the pre and post tests on leg strength of Yogic training group and control group (Seconds)

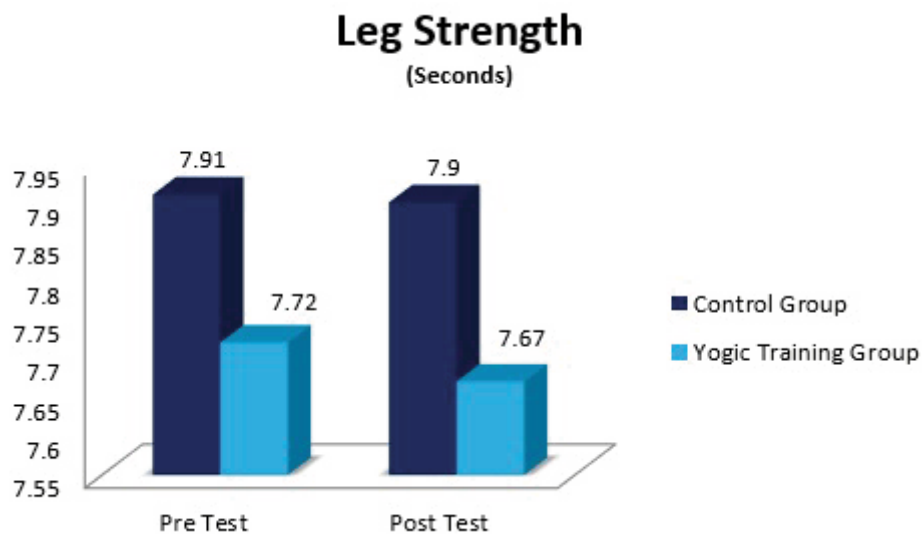

Variable	Groups	Mean		SD		Sd Error	df	‘t’ Ratio
		Pre	Post	Pre	Post			
Leg Strength	Control Group	7.91	7.90	0.45	0.45	0.009	14	0.36
	Yogic Training Group	7.72	7.67	0.60	0.60	0.005		8.19*

*Significance at 0.05 level of confidence.

SD-Standard Deviation, SD Error- Standard Deviation Error, df- Degrees of Freedom

The Table - 1 shows that the mean values of pre-test and post-test of control group on leg strength were 7.91 and 7.90 respectively. The obtained 't' ratio was 0.36, since the obtained 't' ratio was less than the required table value of 2.15 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of experimental groups on leg strength were 7.72 and 7.67 respectively. The obtained 't' ratio was 8.19 since the obtained 't' ratio was greater than the required table value of 2.15 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant. The result of the study showed that there was a significant difference between control group and experimental group in leg strength. It may be concluded from the result of the study that experimental group improved in leg strength due to six weeks of yogic training.

Figure - 1
Bar diagram shows the pre and post test mean values of Control group and yogic training group on leg strength

Arm Strength

The results of the dependent 't'-test on the data obtained for arm strength of the subjects in the pre-test and post-test of the yogic training group and control group have been analyzed and presented in Table 2.

Table – 2
Summary of mean, standard deviation and dependent's' test for the pre and post tests on arm strength of yogic training group and control group (Seconds)

Variable	Groups	Mean		SD		Sd Error	df	't' Ratio
		Pre	Post	Pre	Post			
Arm Strength	Control Group	19.70	19.69	1.68	1.68	0.002	14	1.87
	Yogic Training Group	19.09	19.04	1.24	1.23	0.005		9.24*

*Significance at 0.05 level of confidence

SD-Standard Deviation, SD Error- Standard Deviation Error, df- Degrees of Freedom

The Table - 2 shows that the mean values of pre-test and post-test of control group on arm strength were 19.70 and 19.69 respectively. The obtained 't' ratio was 1.87, since the obtained 't' ratio was less than the required table value of 2.15 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of yogic training group on arm strength were 19.09 and 19.04 respectively. The obtained 't' ratio was 9.24 since the obtained 't' ratio was greater than the required table value of 2.15 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant. The result of the study showed that there was a significant difference between control group and experimental group in arm strength. It may be concluded from the result of the study that experimental group improved in arm strength due to six weeks of yogic training

Figure - 2
Bar diagram shows the pre and post test mean values of Control group and yogic training group on arm strength

Explosive Strength

The results of the dependent 't'-test on the data obtained for explosive strength of the subjects in the pre-test and post-test of the yogic training group and control group have been analyzed and presented in Table 3.

Table – 3
Summary of mean, standard deviation and dependent 't' test for the pre and post tests on explosive strength of yogic training group and control group (Centimeters)

Variable	Groups	Mean		SD		Sd Error	df	't' Ratio
		Pre	Post	Pre	Post			
Explosive Strength	Control Group	12.26	11.93	1.79	1.43	0.23	14	1.43
	Yogic Training Group	11.73	16.26	1.62	1.27			0.36

*Significance at 0.05 level of confidence

SD-Standard Deviation, SD Error- Standard Deviation Error, df- Degrees of Freedom

The Table - 3 shows that the mean values of pre-test and post-test of control group on explosive strength were 12.26 and 11.93 respectively. The obtained 't' ratio was 1.43, since the obtained 't' ratio was less than the required table value of 2.15 for the significant at 0.05 level with 14 degrees of freedom it was found to be statistically insignificant. The mean values of pre-test and post-test of yogic training group on explosive strength were 11.73 and 16.26 respectively. The obtained 't' ratio was 12.47 since the obtained 't' ratio was greater than the required table value of 2.15 for significance at 0.05 level with 14 degrees of freedom it was found to be statistically significant. The result of the study showed that there was a significant difference between control group and experimental group in explosive strength. It may be concluded from the result of the study that experimental group improved in explosive strength due to six weeks of yogic training.

Figure - 3
Bar diagram shows the pre and post test mean values of Control group and yogic training group on arm strength

Discussion on Findings

The investigator had a through and vision that yoga practices on selected strength variables among college men basketball players. The statistical values presented in table proved that there was significant improvement in selected strength variables among college men basketball players due to yogic practices. Obtained 't' value of leg strength is 8.19, arm strength is 9.24 and explosive strength is 12.47 respectively which is greater than the required 't' value to be significant. For the degrees of freedom 2.15 at 0.05 level of confidence. Thus the hypothesis of the study that would be significant improvement due to the yogic training.

Conclusions

Based on the results of the present study the following conclusions.

1. The results of the study showed that there were significant improvements in selected strength variable after six weeks yogic practices among college men basketball players.
2. The nature of the leg strength was significant improvement in yogic training group than the control group.
3. The nature of the arm strength was significant improvement in yogic training group than the control group.

4. The nature of the explosive strength was significant improvement in yogic training group than the control group.

Ahalia International Journal of Advanced Science and Technology

AIJAST

Call for Papers

Ahalia International Journal of Advanced Science and Technology (AIJAST) is going to launch its second issue i.e. Vol. 1 Issue 2 for the period of April - June 2021. We would like to invite you to contribute a Research Paper for publication in AIJAST for the above referred issue. The Ahalia International Journal of Advanced Science and Technology, is a peer reviewed, quarterly international journal that provides publication of articles in all areas of engineering, science, technology, medicine, environment, management etc., through research and its relevant appropriation and inferential application. The first few editions will be online and thereafter will be both online and print. The articles should be in proper format. Submissions must be original and should not have been submitted or published previously anywhere else.

Submission guidelines are available at <https://ahalia.ac.in/aijast/>

*Submit your article to
ahaliajournal@ahalia.ac.in*

*Last Date for Submission
31st May 2021*

+91 9496000133

Sathyabama Institute of Science and Technology, Chennai, India.

J K Periasamy

Associate Professor, Department of Computer Science and Engineering,
Sri Sairam Engineering College, Chennai, India.

ABSTRACT

Separately, the Internet of Things (IoT) and Artificial Intelligence (AI) are ground-breaking advances. At the point when we consolidate AI and IoT, we get AIoT - the artificial intelligence of things. We can consider IoT gadgets as the digital sensory method whilst AI is the brain of a framework. In this article, we are analyzing about AIoT and analyzing about the applications and real time examples of AIoT method.

Key words: Internet of Things, Artificial Intelligence, Drone, Fleet Management and Autonomous Robot.

Cite this Article: R Revathy, Murugananth Gopal Raj, M Selvi and J K Periasamy, Analysis of Artificial Intelligence of Things. *International Journal of Electrical Engineering and Technology*, 11(4), 2020, pp. 275-280.

1. INTRODUCTION

The Artificial Intelligence of Things (AIoT) is the mixture of artificial intelligence (AI) innovations with the Internet of Things (IoT) communications to realize increasingly effective IoT operations, get better human machine communications and improve information organization and analytics. AI may be utilized to convert IoT data into valuable data for enhanced result making forms, hence making a base for more up to date innovation, for example, IoT Data as a Service (IoTDaaS).

AIoT is transformational with equally favorable for the two sorts of innovation as AI adds significance to IoT by machine learning abilities as well as IoT adds significance to AI by connectivity, gesturing and information replace. Since IoT systems swell all through main enterprises, there would be gradually more value of human-situated as well as machine-created formless data. AIoT may offer help for data analytics clarifications that may generate significance out of this IoT created information [1].

With AIoT, AI is installed into communications tools, for example, courses, chipsets along with edge processing, every consistent through IoT systems. APIs are then utilized to broaden interoperability among elements at the gadget stage, software stage as well as platform stage. These elements will concentrate mainly on enhancing framework and method process with removing significance from information.

While the conception of AIoT is immobile moderately novel, a lot of prospects exist to get better trade verticals, for example, endeavor, trade and customer item and overhaul areas, and will carry on to occur by its development. AIoT can be a feasible key to take care of existing prepared issues, for example, the cost connected by compelling human capital management (HCM) or the unpredictability of flexibly chains as well as conveyance models.

To completely understand AIoT, you should start with the IoT. At this position when "things, such as, wearable gadgets, refrigerators, digital assistants, sensors as well as additional gear are connected to the internet, may be supposed through dissimilar devices with collect along with practice data, you have the IoT. AI is the stage at which a structure may conclude a set of tasks or learn from data in a way that emerges to be canny. In this way, when AI is additional to the IoT it means that those tools may analyze data with make decisions as well as act on that data with no involvement by humans.

These are "smart" tools, as well as they assist force efficiency along with adequacy. The intelligence of AIoT enables data analytics that is then utilized to enhance a structure as well as generate superior and trade experiences along with create data that helps with making enhanced decisions as well as that the structure may learn from.

2. BENEFITS OF AIOT

AIoT directs to a wide variety of advantages for corporations and customers like a practical involvement, modified understanding, and insightful mechanization [2]. Here are the absolute mainly fashionable advantages of joining these two problematic advancements to the organizations:

Enhancing Equipment Effectiveness: AI in IoT chomps the steady flow of information and identifies the outlines not beguiling on basic estimates. Additionally, machine learning combined by AI may anticipate the process states as well as identify the constraints to be altered to guarantee perfect results. Henceforth, shrewd IoT suggests an understanding into which procedures are superfluous as well as tedious, and which assignments may be tweaked to improve productivity. Google, for instance, fetches the intensity of AI into IoT to decrease its information community breezing costs.

Better Threats Supervision: Combining AI with IoT encourages organizations to realize and foresee a wide variety of dangers and computerize for the brief reaction. In this way, it permits them to all the more likely handle financial misfortune, representative security, and digital risks. Fujitsu, such as, guarantees laborer security through appealing AI for considering information sourced from linked wearable gadgets.

Activating Original and Superior Products & Services: Natural Language Processing (NLP) is showing signs of improvement at permitting individuals to converse with gadgets. Indisputably, IoT and AI jointly may straightforwardly make innovative items or improve

existing items and services through allowing the trade to quickly development and evaluate the data. Moves Royce, for example, maps to influence AI innovations in the execution of IoT-enabled airplane motor preservation facilities. In reality, this loom will maintain to speck guides and find equipped bits of knowledge.

Enlarge IoT Scalability: IoT gadgets range from cell phones as well as top of the line PCs to low-end sensors. Be that as it may, the mainly general IoT environment incorporates low end sensors, which proposes surges of information. AI-fueled IoT environment evaluates and reviews the information from one gadget prior to moving it to different gadgets. By itself, it diminishes huge volumes of information to useful stage and permits connecting countless IoT gadgets.

Removes Expensive Unexpected Downtime: In certain parts like seaward oil and gas as well as manufacturing industrial, hardware collapse may bring about expensive unexpected vacation. The prescient preservation by AI enabled IoT permits you to anticipate the gear breakdown in proceed and calendar systematic preservation methodology. Thus, you can shun the reactions of vacation.

3. REALISTIC MODELS OF AIOT

The combo of IoT as well as elegant frameworks creates AIoT a ground-breaking and significant instrument for numerous functions [3]. Here are some:

3.1. Drone Traffic Monitoring

In a smart city, there are numerous realistic employments of AIoT, counting traffic monitoring by drones. In the event that traffic can be screened in instantaneous as well as alterations to the traffic stream can be taken, jamming can be decreased. At the point when drones are conveyed to supervise a huge region, they can broadcast traffic information, along with AI can investigate the information as well as create results on how to finest ease traffic jamming by alterations as far as possible and time of traffic lights with no human inclusion. The ET City Brain, a result of Alibaba Cloud, streamlines the utilization of town assets through utilizing AIoT. This framework can recognize accidents, unlawful parking, as well as can alter traffic lights to assist ambulances with getting to patients who require support quicker.

Figure 1 Traffic Monitoring using Drone

3.2. Smart Trading

In smart trade surroundings, a camera framework outfitted by PC visualization abilities can utilize facial identification to recognize clients when they amble by the entryway. The framework collects intel about clients, counting their sexual orientation, item inclinations, traffic stream and other, evaluates the information to correctly anticipate customer performance and then utilizes that data to create results about hoard process from advertising to item assignment and different results. Such as, if the framework distinguishes that the mass of clients walking into the amass are Millennials, it may promote out item posters or in-store particulars that demand to that demographic, along these lines driving up sales.

3.3. Autonomous Vehicles and Fleet Management

AIoT is utilized to in fleet management nowadays to assist supervise a fleet's motor vehicles, diminish energy costs, trail vehicle preservation, and to recognize risky driver performance. By IoT gadgets, for example, GPS as well as different sensors with an AI framework, corporations are capable to supervise their fleet superior appreciation to AIoT.

Figure 2 Fleet Management for Autonomous Vehicles

One more way AIoT is utilized nowadays is by autonomous vehicles, for example, Tesla's autopilot frameworks that utilization sonars, radars, GPS, as well as cameras to collect information about driving situations with then an AI framework to create choices about the information the IoT gadgets are meeting.

3.4. Office Buildings

One more area where AI and the IoT cross is in smart places of business. A few companies decide to fit a system of elegant ecological sensors in their place of business. These sensors may recognize what employees are available and regulate temperatures as well as lighting consequently to get better vitality productivity. In an additional utilization stage, a smart structure can manage building admission by facial identification innovation. The mixture of linked cameras with AI that can evaluate images captured in real-time beside a database to figure out who ought to be approved right to use to a structure is AIoT busy working. In a related way, representatives wouldn't have to check in, or presence for compulsory gatherings would not have to be finished, as the AIoT framework gets care of it.

3.5. Autonomous Delivery Robots

Related to how AIoT is utilized by autonomous vehicles, independent conveyance robots are a new instance of AIoT in real life. Robots have sensors that collect data about the

surroundings the robot is navigating along with then create second to-second choices about how to react by its onboard AI platform.

Figure 3 Autonomous Delivery Robot

4. CONCLUSION

In this article titled “Analysis of Artificial Intelligence of Things”, we have discussed about the brief introduction of AIoT, how it will work, what are the benefits of AIoT with real time example and also discussed about the realistic models of AIoT. In future, we can use this AIoT technique in many equipment’s implementation and also we can use this AIoT technique for bringing better performance of many appliances.

Abstract--- Linear speed-torque characteristics feature of PMDC motor makes it to be used in orthopedic surgeries widely. The PI controller based conventional speed control schemes employed for PMDC motor has the disadvantages of poor steady and transient state characteristics. Several algorithms have been attempted to enhance the performance of this speed control system so far. This paper proposes antlion based meta heuristic algorithm embedded speed control system to improve the performance of the chopper driven PMDC motor. The proposed scheme determines the optimum pulse width required to drive the chopper circuit and controls the speed of the motor. Simulation studies of the proposed model using Matab/Simulink reveals its improved steady and transient state characteristics.

Keywords--- Antlion, Ants, ALO, Building Trap, Elitism, Random Walk, PMDC Motor, Steady State, Transient State.

I. Introduction

In orthopedic surgeries, Permanent Magnet DC (PMDC) motors are being used as it exhibits linear speed-torque characteristics. These motors find wide applications in bio-medical engineering which includes robot manipulators, surgical simulators etc. These applications need precise control of speed for some of the load conditions. Using the surgical simulators, novice surgeons practice Osteosynthesis, which is the phenomenon of joining fractured bones with metal rods and screws. They practice Osteosynthesis in cadaver bones using motorized tools. Conventional chopper driven PMDC motor are employed in these motorized tools.

Many researchers have developed various efficient training tools for Osteosynthesis. Micro-vibrated robot based controller developed by Shih-Tseng Lee et al (2001) is most popular among them. This micro-vibrated model used PMDC motor with current feedback control loop for drilling and tightening purposes. A computer assisted training simulator was proposed by Ming-Dar Tsai et al (2007). Thomas (2008) fabricated an automatic screw driver and Ann Majewicz et al (2011) designed and developed a haptic simulator. All these tool kits utilized chopper driven PMDC motor and assisted the novice surgeons to practice surgical operations easily.

In general, torque and speed are the required parameters to drill the bones and insert the screws in bones. The values of these parameters vary depending on the nature of the bones and mode of operation as well. Drilling and Screwing are the two modes of operation that require different speed and torque values. Drilling needs less torque, whereas screwing and tightening need more. Careful operation of these modes is needed; else it may lead to additional fracture in the bones. At the outset, precise control of PMDC motor is required to provide efficient training.

Several control algorithms have been suggested and developed by various researchers for the speed control of PMDC motor. The problems associated with these algorithms are undesirable overshoot and longer settling times. As the surgical operations are carried out only for a very short duration, the control system is expected to provide stable operation within a brief settling time. To have these features, this paper suggests a meta heuristic algorithm based on Antlion phenomenon for the speed control of PMDC motor. The proposed algorithm provides enhanced transient and steady state stability of the system of interest.

II. Related Works

The computer assisted orthopedic surgical simulators employed with PMDC motor consist of a chopper drive to control the motor operation. Nitai Pal et al (2012) suggested chopper driven PMDC motor for rock drilling applications. Muruganath and Vijayan (2012) analyzed the performance of chopper driven PMDC motor with

conventional PI, PID and anti-wind up controllers. Low cost microcontroller-based speed control technique has been proposed by Pithwa and Parek (2012). Image processing assisted robotic arm has been suggested by Vipul Gohil et al (2013) for the automated surgery applications. Fuzzy logic-based drive has been recommended for the performance enhancement by Murugananth and Vijayan (2015). Experimental results of fuzzy tuned anti-wind up PI controller devised by Murugananth, Samidurai et al (2015) validate its superior operating characteristics when compared to conventional PI controller. Genetic Algorithm and Brain Emotional Logic based intelligent Controller (BELBIC) have been suggested by Vijayakumar et al (2016) and Muthukrishnan et al (2016) to improve the performance of chopper driven PMDC motor. Murugananth and Manickavasagam (2019) proposed hybrid fuzzy tuned PI controller based on raindrop algorithm.

All these controllers were developed with a focus of improving the performance of chopper driven PMDC motor in respect of its steady and transient state operations. However, the performance of these controllers under variable load conditions is not appreciable. To overcome this problem, this study proposes a controller driven by antlion optimization based algorithm. The proposed controller aids to improve the transient and steady state performance of the chopper drive system to a significant extent even under the variable load conditions.

III. Conventional Drive System

The equivalent circuit and its mathematical model of the PMDC motor have been shown in Figure 1 and Figure 2 respectively. The model has been developed using the equations (1) to (4).

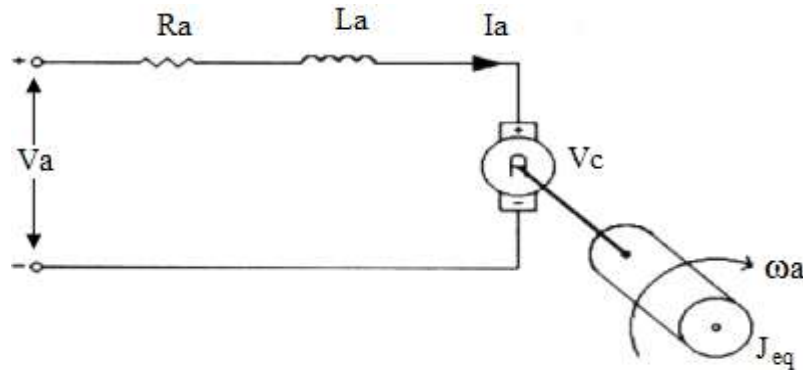

Figure 1: Equivalent Circuit of PMDC Motor

$$V_a = V_c + I_a R_a + L_a \frac{dI_a}{dt} \tag{1}$$

$$V_c = K_1 \omega_a \tag{2}$$

$$T_E = T_L + B \omega_a + J \frac{d\omega}{dt} \tag{3}$$

$$T_E = K_2 I_a \tag{4}$$

Where,

- V_a - armature supply voltage in V
- V_c - induced voltage in V
- R_a - armature resistance in Ohms
- L_a -armature inductance in H
- I_a - armature current in A
- K_1 -voltage constant in volts sec/rads
- ω_a - angular speed in rads/sec
- T_E - electromagnetic torque developed in Nm
- T_L - load torque in Nm
- J_{eq} - Moment of Inertia in $N.m^2/s^2$
- B -damping Coefficient in Nms
- K_2 - torque constant in Nm/A

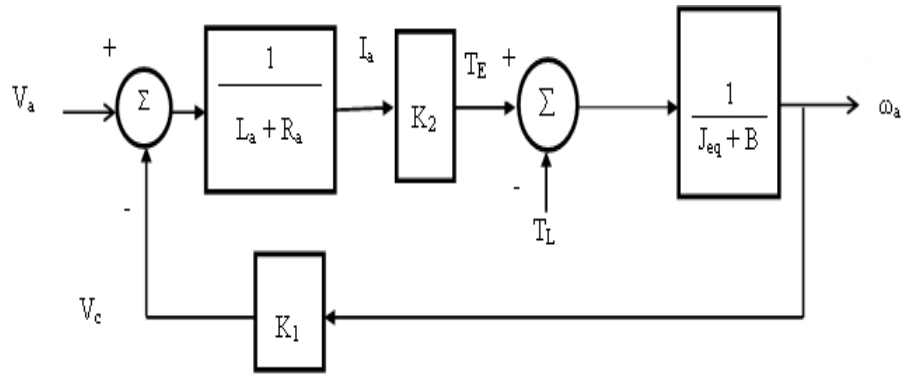

Figure 2: Mathematical Model of PMDC Motor

Figure 3 portrays the closed loop chopper drive proposed by Muruganath et. al (2012a & 2012b). This chopper drive utilizes a PI controller, whose gain values are tuned using Ziegler – Nichols method. The performance of this drive is not satisfactory in terms of peak overshoot and steady state error. Hence the antlion optimization algorithm based drive has been proposed for the significant improvement in performance.

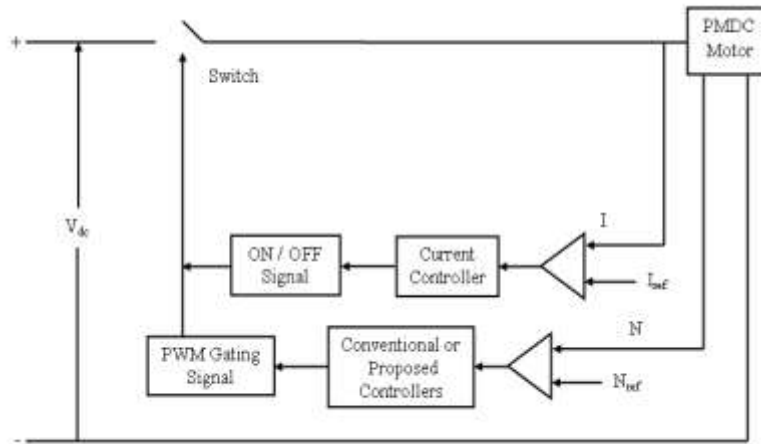

Figure 3: Chopper Driven PMDC Motor

IV. Antlion Optimization (ALO)

4.1 Background Study of ALO

Antlion Optimizer (ALO) has been proposed by Mirjalili and Seyedai (2015). Prasad and Ram (2016) proposed antlion optimization for the tuning of PID controller to achieve optimal speed control with torque ripple minimization of Synchronous Reluctance Motor (SRM) drive system. Kamaraj Premkumar et al (2017) suggested antlion optimized fuzzy PID supervised on-line recurrent fuzzy neural network based controller for brushless DC motor. Dinakara Prasad Reddy et al (2018) applied ALO to fix the optimal location and size of DG sets to be integrated with distribution generation system. These studies led to the use of ALO to enhance the performance of the chopper driven PMDC motor used in orthopedic surgeries.

4.2 Life Cycle of Antlions

Antlions live in two phases: larva and adult. When they are in larva stage, their hunting mechanism is much interesting. Figure 4 (a) and 4 (b) depicts the larva and adult stages of antlions respectively.

(a) Larva

(b) Adult

Figure 4: Life Cycle Stages of Antlions

As shown in the figure 5, a small cone-shaped sand pit traps is made by antlions to trap the ants. Antlions sit under the pit and wait for prey to be trapped. Once when the prey is caught the prey's flesh is consumed. The leftovers are thrown outside the pit by the antlion. Then it amends the pit for the next hunt. While the antlions are hungry, they dig a bigger pit. This is the main inspiration for ALO algorithm.

Figure 5: Sand Pit Trap

4.3 Antlion Optimization

ALO is a meta-heuristic algorithm. It mathematically relates the interaction of ants and antlions. It optimizes the problems based on the random walk, random selection of agents, building traps, entrapment of ants in traps, catching preys and re-building traps. The roulette wheel and random walks of ants in ALO optimizer can eliminate local optima. Random walk of ants are given by

$$X(t) = [0, \text{cumsum}(2r(t_1) - 1), \text{cumsum}(2r(t_2) - 1), \dots, \text{cumsum}(2r(t_n) - 1)] \quad (5)$$

Where, *cumsum* is calculating cumulative sum, *n* is maximum number of iterations; *t* is step of random walk.

$$r(t) = \begin{cases} 1 & \text{if } rand > 0.5 \\ 0 & \text{if } rand < 0.5 \end{cases} \quad (6)$$

Where, *rand* is random generator between 0 & 1. Based on eqn. 6, the random walk can be made inside the search space as given by eqn. 7.

$$X_i^t = \frac{(X_i^t - a_i) \times (d_i^t - c_i^t)}{(b_i - a_i)} + c_i^t \quad (7)$$

Where, *a_i* & *b_i* are the minimum and maximum values of random walk of *ith* variable. *c_i* & *d_i* are the minimum and maximum of *ith* variable in the *tth* iteration. The location of ants and corresponding fitness function matrix are given below:

$$M_{Ant} = \begin{pmatrix} A_{1,1} & A_{1,2} & \dots & \dots & A_{1,d} \\ A_{2,1} & A_{2,2} & \dots & \dots & A_{2,d} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ A_{n,1} & A_{n,2} & \dots & \dots & A_{n,d} \end{pmatrix} \quad (8)$$

$$M_{OA} = \begin{bmatrix} f(A_{11}, A_{22}, \dots, A_{1d}) \\ f(A_{21}, A_{22}, \dots, A_{2d}) \\ \vdots \\ f(A_{n1}, A_{n2}, \dots, A_{nd}) \end{bmatrix} \quad (9)$$

Where, *M_{OA}* represents fitness values of location of ants matrix *M_{Ant}*. If ants and antlions are hidden in search area then the corresponding location and fitness matrices of antlions are given by

$$M_{Antlion} = \begin{pmatrix} A_{1,1} & A_{1,2} & \dots & \dots & A_{1,d} \\ A_{2,1} & A_{2,2} & \dots & \dots & A_{2,d} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ A_{n,1} & A_{n,2} & \dots & \dots & A_{n,d} \end{pmatrix} \tag{10}$$

$$M_{OAL} = \begin{bmatrix} f(A_{11}, A_{22}, \dots, A_{1d}) \\ f(A_{21}, A_{22}, \dots, A_{2d}) \\ \vdots \\ f(A_{n1}, A_{n2}, \dots, A_{nd}) \end{bmatrix} \tag{11}$$

Where, M_{OAL} matrix represents fitness values of location of ant lions.

Building Trap

To get higher probability of catching ants roulette wheel is used.

Trapping in Ant Lion Pits

Eqn. 12 depicts the mathematical model of trapping

$$\begin{aligned} c_i^t &= Antlion_j^t + c^t \\ d_i^t &= Antlion_j^t + d^t \end{aligned} \tag{12}$$

Where, c_i^t d_i^t are minimum and maximum of all variables at i^{th} iteration. c^t and d^t are minimum and maximum variables for i^{th} ant. $Antlion_j^t$ is the ant position of selected antlion.

Sliding Ants Towards Ant Lions

In order to slide ants towards ant lions, ant lions shoot sand outwards. The radius of ants' random walks hypersphere is decreased adaptively, as depicted in Figure 6.

Figure 6: Sand Pit Traps with Remains of Ants

Equations 13 depict the mathematical model as

$$\begin{aligned} C^t &= c^t/I \\ D^t &= d^t/I \end{aligned} \tag{13}$$

Where, $I = 10 t/T$, t is current iteration and T is maximum number of iterations.

Catching the Prey and Rebuilding the Pit

Antlion catches its prey when it becomes fitter than its associated antlion. After catching the prey the antlion update its position to the latest position of the hunted ant. This is expressed in eqn. 14.

$$Antlion_j^t = Ant_i^t \text{ if } f(Ant_i^t) > f(Antlion_j^t) \tag{14}$$

Elitism

Evolution algorithms are expected to provide best solutions. The best antlion obtained from the successive iterations is saved and considered as elite. It is the fittest antlion and should be able to affect the movement of the ants during iteration. It is assumed that every ant randomly walks around a selected antlion by the roulette wheel and the elite are given by eqn. 15.

$$Ant_i^t = \frac{R_A^t + R_E^t}{2} \tag{15}$$

Where, R_A^t and R_E^t are random walks near by the antlion by roulette wheel, elite at i^{th} iteration, Ant_i^t is the position of i^{th} ant at the end of t^{th} iteration

V. Proposed ALO Driven Chopper System

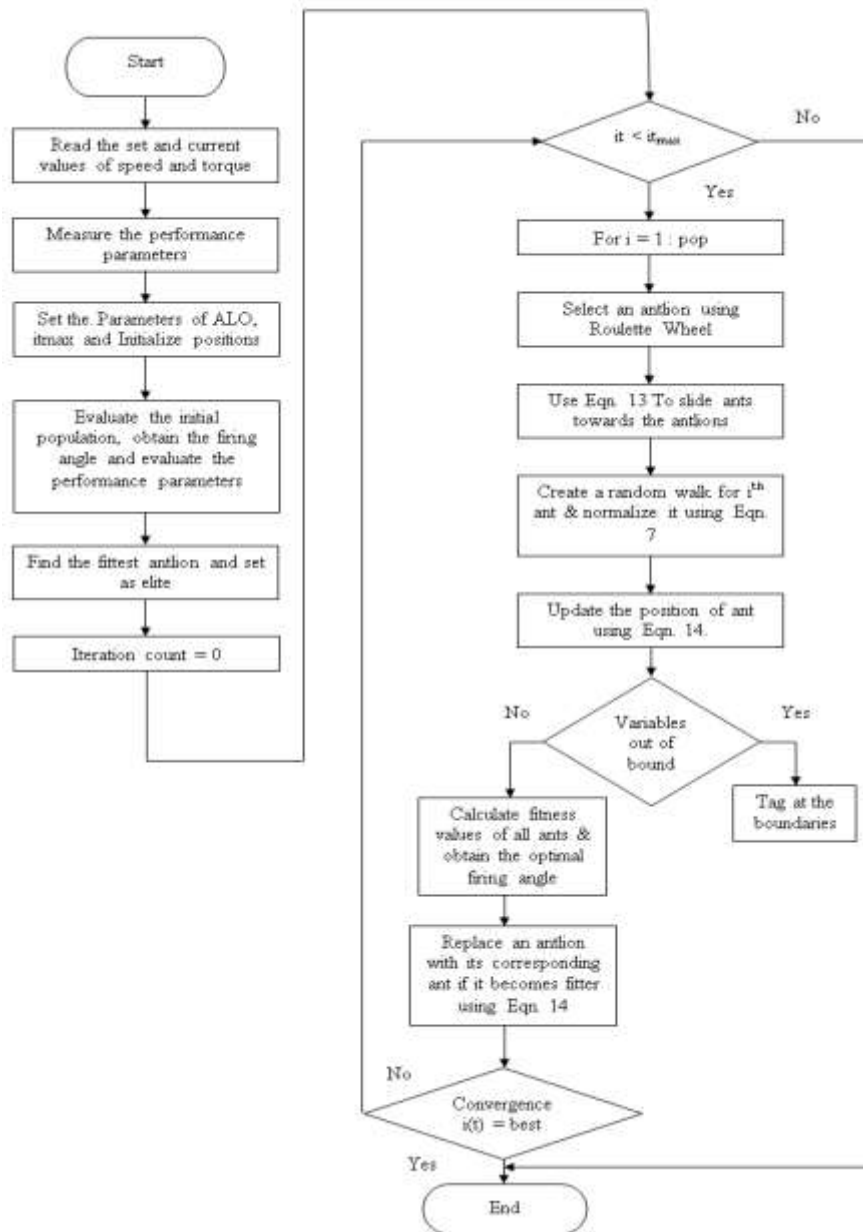

Figure 7: Flowchart of Proposed ALO Algorithm

Figure 7 illustrates the flowchart of the proposed ALO algorithm to generate the appropriate pulse width. The pulses or control signals required for optimum speed are processed by the proposed algorithm. The current speed (rpm) and set speed (rpm) values are taken as input function to the system. The parameters for the ALO are fixed and the ant positions are fixed. The ants make random walk towards the prey. Catches them and return backs to the pit. Once the antlion gets the prey it consumes it and throw the prey's flesh and amends the pit. By the same way, from the measured performance parameters, based on the equations 5 to 15, the control pulses are generated. The performance indices are peak overshoot, steady state error and integral error based on which the optimal switching pulse is obtained. When they are minimized, the optimal values are obtained. The optimum switching pulses offer lowest values of peak overshoot, steady state error and integral of absolute error which are the desired optimal solutions.

VI. Simulation Results

The response of the proposed system is given in Figure 8. The comparative analysis of the conventional PI and proposed ALO algorithm driven controller are depicted in Figure 9, for a set speed of 1000 rpm. It is evident from the analysis that the peak overshoot offered by the proposed system is reduced by 32.5% when compared with the conventional PI system. The peak overshoot of the proposed system is 14.7% whereas in the case of the conventional PI controller it is 21.4%.

Figure 8: Response of ALO Algorithm

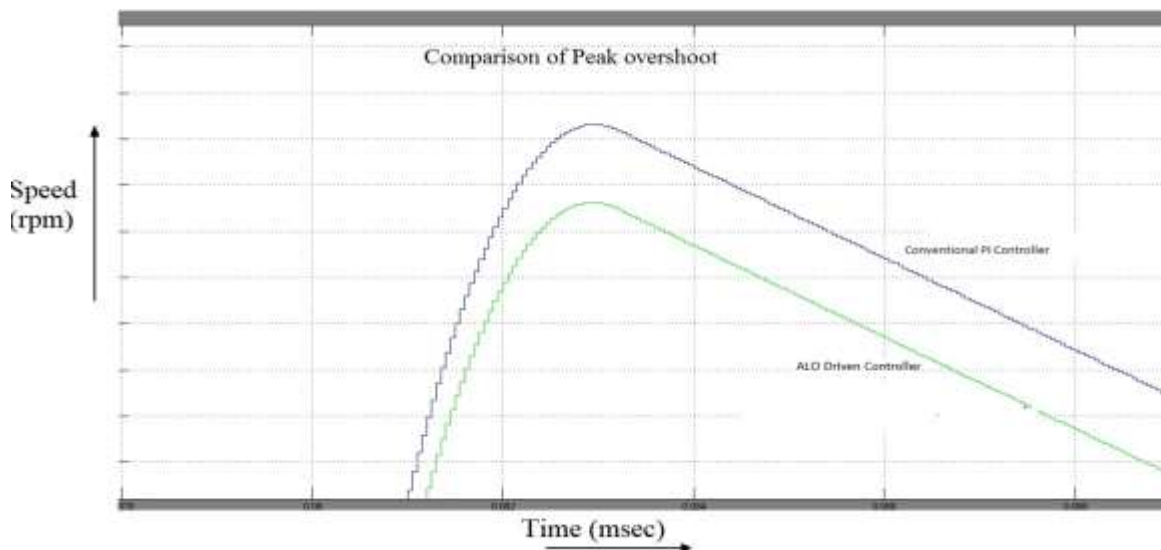

Figure 9: Peak Overshoot Comparative Analysis

Table 1: Performance Comparison of Conventional PI and ALO Driven Controllers

Set speed rpm	Peak Overshoot %		Steady State Error		Integral Absolute Error	
	PI Controller	ALO Controller	PI Controller	ALO Controller	PI Controller	ALO Controller
750	24	16.2	11	6.3	9	4.5
1000	21.4	14.7	7.5	5.4	8.82	4.4
1200	20.2	12.6	7	4.2	8.2	3.9

The performance indices viz. peak overshoot, steady state error and the deviation in the error for various set speed values are tabulated for both the conventional PI and proposed ALO driven controller as in Table 1. It is observed that increase in set speed decreases the control parameters of interest. The proposed ALO driven controller reduces the peak overshoot offered by the conventional controller by 25% even at lower speeds. At higher speeds, it has been more than 33%. The proposed controller reduces the steady state error for about 30 to 35% at all speeds. 50% reduction of integral absolute error has been observed with the proposed controller compared to its conventional counterpart.

VII. Conclusion

Antlion Optimization algorithm-based controller has been attempted in this paper for the control of PMDC motor used in orthopedic surgical simulators. The simulation results and the corresponding comparative analysis revealed that there is a significant improvement in the transient and steady-state response of the proposed system. Hence, it is concluded that the proposed Antlion algorithm driven chopper drive has an edge over its conventional counterpart as far as the functional capabilities are concerned.

Asymmetrical Seven Level CHB Inverter based Voltage Compensation Device for an 11kV Distribution System

G Muruganath¹, Swetha R²

¹Professor, ²Assistant Professor, Department of EEE, Ahalia School of Engineering and Technology, India

Abstract: This paper presents a Distribution Static Compensator (DSTATCOM) with a sinusoidal pulse width modulated (SPWM) Cascaded H Bridge (CHB) multilevel inverter for shunt compensation of distribution system. The advantages of DSTATCOM are power factor improvement, voltage regulation and harmonic mitigation in distribution line and load balancing. CHB inverters are used widely because of their simplicity, modularity and reduced switching losses. Here a seven level cascaded H bridge based DSTATCOM is considered for the voltage sag compensation of an 11 kV distribution system. The software used is MATLAB. The performance of multilevel inverter is investigated and Total Harmonic Distortion (THD) is noticed.

Abstract: In this study, artificial neural network models have been developed for concrete and fly ash concrete slabs of sizes 1000mm x 1000mm with various thickness 150mm, 200mm, 250mm and 300mm. The data used in the artificial neural networks includes temperature differential (°C), thickness of slab (mm), Modulus of Elasticity (MPa) and Poisson's ratio were taken as input layers and an output layer which is temperature stresses, the test results have shown that NN have strong potential for predicting the temperature stresses in fly ash concrete pavements.

I. INTRODUCTION

Blockchain was invented by a person (or group of people) using the name Satoshi Nakamoto in 2008. A blockchain, originally blockchain is a growing list of records, called blocks that are linked using cryptography. Each block contains a cryptographic hash of the previous block, a timestamp, and transaction data. A blockchain is resistant to modification of the data. It is "an open, distributed ledger that can record transactions between two parties efficiently and in a verifiable and permanent way". For use as a distributed ledger, a blockchain is typically managed by peer to peer network collectively adhering to protocol for inter-node communication and validating new blocks.

Blockchain is a digital-ledger-based technology developed to change the perspective of the digital transactions, or specifically, to replace them. Blockchain is defined as a distinct, decentralized distributed ledger that includes all transactions records related to participating members. Blockchain transactions are created and stored in chronological order, allowing digital assets (such as digital currency and digital data) to be tracked by participants without central record-keeping. One of the key features in blockchain is that participating nodes in the network will hold a copy of the full blockchain. All transactions on the blockchain must be approved because transactions are only valid under the consensus agreement of the participating members. In addition, all transactions are trackable, making fraudulent transactions impossible to bypass. When a user (user A) wants to make a transaction to another user (user B) using blockchain, a new block is created to include the transaction. Each transaction is broadcasted across network nodes to verify it. If the new transaction is verified, the new block is added to the blockchain and distributed across network nodes so that other nodes will update their blockchain.

In this new era crowdfunding is done through blockchain technology. Crowdfunding has become an extremely useful alternative to venture capital, and has also

allowed non-traditional projects, such as those started by in-need families or hopeful creatives, a new audience to pitch their cause. Crowdfunding has disrupted the way of financing and allowed the startups to raise funds without much hustle and bureaucracy. In the existing model, Pool of people contribute small amounts of money towards a project or cause and expect some financial or non-financial returns. A crowdfunding platform takes a commission and matches the needs and expectations of funders and fundraisers. Blockchain technology is a decentralized ledger, more efficient, safe and tamper-proof system of nodes in connection. Introduction of blockchain in crowdfunding will make it more reliable, transparent, trusted, decentralized, cost efficient and convenient. A crowdfunding platform which was acting as an intermediary before will only provide the technology and name is its own cryptocurrency which will act as a medium of transaction and exchange. Fundraisers will generate their own currency and everyone on the network will be notified about the project. Funders will buy this cryptocurrency to claim its share in the project and can withdraw any time by selling the currency and losing the share in a project or transferring it to another project. Blockchain can further improve this unique and contemporary way of raising funds by making out more reliable and transparent.

II. BLOCKCHAIN

A blockchain, originally block chain, is a growing list of records, called blocks, that are linked using cryptography. Each block contains a cryptographic hash of the previous block, a timestamp, and transaction data. By design, a blockchain is resistant to modification of the data. Blockchain is resistant to modification of the data. It is "an open, distributed ledger that can record transactions between two parties efficiently and in a verifiable and permanent way". For use as a distributed ledger, a blockchain is typically managed by a peer-to-peer network collectively adhering to a protocol for inter-node communication and validating new blocks. Once recorded, the data in any given block cannot be altered retroactively without alteration of all subsequent blocks, which requires consensus of the network majority. Although blockchain records are not unalterable, blockchains may be considered secure by design and exemplify a distributed computing system with high Byzantine fault tolerance. Decentralized consensus has therefore been claimed with a blockchain. Blockchain was invented by a person (or group of people) using the name Satoshi Nakamoto in 2008 to serve as the public transaction ledger of the cryptocurrency bitcoin. The identity of Satoshi Nakamoto is unknown. The invention of the blockchain for bitcoin made it the first digital currency to solve the double-spending problem without the need of a trusted authority or central server. The bitcoin design has inspired other applications, and blockchains that are readable by the public are widely used by cryptocurrencies. Blockchain is

considered a type of payment rail. Private blockchains have been proposed for business use. Sources such as Computerworld called the marketing of such blockchains without a proper security model.

The first work on a cryptographically secured chain of blocks was described in 1991 by Stuart Haber and W. Scott Stornetta. They wanted to implement a system where document timestamps could not be tampered with. In 1992, Bayer, Haber and Stornetta incorporated Merkle trees to the design, which improved its efficiency by allowing several document certificates to be collected into one block. The first blockchain was conceptualized by a person (or group of people) known as Satoshi Nakamoto in 2008. Nakamoto improved the design in an important way using a Hashcash-like method to timestamp blocks without requiring them to be signed by a trusted party and introducing a difficulty parameter to stabilize rate with which blocks are added to the chain. The design was implemented the following year by Nakamoto as a core component of the cryptocurrency bitcoin, where it serves as the public ledger for all transactions on the network. In August 2014, the bitcoin blockchain file size, containing records of all transactions that have occurred on the network, reached 20 GB (gigabytes). In January 2015, the size had grown to almost 30 GB, and from January 2016 to January 2017, the bitcoin blockchain grew from 50 GB to 100 GB in size. The ledger size had exceeded 200 GiB by early 2020.

A blockchain is a decentralized, distributed, and oftentimes public, digital ledger that is used to record transactions across many computers so that any involved record cannot be altered retroactively, without the alteration of all subsequent blocks. This allows the participants to verify and audit transactions independently and relatively inexpensively. A blockchain database is managed autonomously using a peer-to-peer network and a distributed timestamping server. They are authenticated by mass collaboration powered by collective self-interests. Such a design facilitates robust workflow where participants' uncertainty regarding data security is marginal. The use of a blockchain removes the characteristic of infinite reproducibility from a digital asset. It confirms that each unit of value was transferred only once, solving the long-standing problem of double spending. A blockchain has been described as a value-exchange protocol. A blockchain can maintain title rights because, when properly set up to detail the exchange agreement, it provides a record that compels offer and acceptance.

Blockchain technology can be integrated into multiple areas. The primary use of blockchains today is as a distributed ledger for cryptocurrencies, most notably bitcoin. There are a few operational products maturing from proof of concept by late 2016. Businesses have been thus far reluctant to place blockchain at the core of the business structure.

Major portions of the financial industry are implementing distributed ledgers for use in banking, and according to a September 2016 IBM study, this is occurring faster than expected. Banks are interested in this technology because it has potential to speed up back office settlement systems. Banks such as UBS are opening new research labs dedicated to blockchain technology in order to explore how blockchain can be used in financial services to increase

efficiency and reduce costs. Berenberg, a German bank, believes that blockchain is an "overhyped technology" that has had a large number of "proofs of concept", but still has major challenges, and very few success stories. The blockchain has also given rise to Initial Coin Offerings (ICOs) as well as a new category of digital asset called Security Token Offerings (STOs), also sometimes referred to as Digital Security Offerings (DSOs). STO/DSOs may be conducted privately or on a public, regulated stock exchange and are used to tokenize traditional assets such as company shares as well as more innovative ones like intellectual property, real estate, art, or individual products. A number of companies are active in this space providing services for compliant tokenization, private STOs, and public STOs. Currently, there are at least four types of blockchain networks — public blockchains, private blockchains, consortium blockchains and hybrid blockchains.

III. BLOCKCHAIN BASED CROWDFUNDING

Crowdfunding is the practice of raising funds by a crowd for an idea or project by contributing relatively amount individually in 1997, crowdfunding become popular through the Marillion, a British rock band which obtained funds from their fans via the Internet for a North American tour there are four types of crowdfunding

A. Equity-based crowdfunding

In this type of crowdfunding, the company can sell its shares to the investor. so the injustice can expect some ownership in return to their contribution. A larger amount of money is invested by the investors instead of a smaller amount of Investments

B. Debt-based crowdfunding

It is the process of investing money in a project or company in debt. the invested amount must be returned in a given period with its interest amount. It resembles traditional Finance with a loan offered by a bank, the difference is multiple individuals or groups are raising funds.

C. Reward-based crowdfunding

Investors get rewards based on the successful completion of the project. The rewards may be non-financial it can capture the hearts of your customers and snowball in popularity

D. Donation-based crowdfunding

It is the type of providing fund without expecting anything in return the fund is raised only based on interest on the idea or project. Implementation of blockchain-based crowdfunding will ensure the security of the fund that is a tamper-proof system of nodes in connection. As the blockchain is immutable the transaction will be corruption free, transparent and decentralized. Ether is used as the cryptocurrency that is generated from the ethereum platform which is an open-source public blockchain-based distributed computing platform and operating system featuring smart contract functionality. ethereum uses accounts and balances in a manner called state transactions

Crowdfunding is implemented using the trending and emerging technology called blockchain using Ethereum. It is a public blockchain network. As the blockchain is

decentralized any project gets an opportunity to present its ideas and collect funds. There will be miners who verify the transaction to earn Ether which is a crypto token that fuels the network. Ownership in a small amount of the project will promote the investors as the blockchain could rely on asset tokenization. Anyone can fund the project around the world without the fundamental limitations of other crowdfunding platforms. Cryptography can be created with the two methods first one is the asymmetric cryptography method and is symmetric cryptography method. In the blockchain, we follow asymmetric cryptography.

Keccak256 belongs to the primitive cryptographic family which includes SHA-3. It is based on a novel approach based on random permutation or function and allows inputting any amount of data and outputting any amount of data that acts as a pseudorandom function regarding all the previous inputs. In sponge terminology, the operation is called as absorbing and squeezing.

To validate the authenticity and integrity we use a mathematical technique called Digital signature. It provides high security more than the handwritten signature or stamped seal. It confirms the identity and status of the transaction and promises assurance. The private key is used by the one who creates a digital signature to encrypt signature related data, decryption can be only done using the signer's public key. The digital signature includes security features like:

- Asymmetric cryptography
- Pins, password, and codes
- Timestamping
- Cyclic redundancy checking
- Certificate authority validation
- Trust service provider validation

There are typically three algorithms involved in digital signature processes such as key generation, signing, and verification. The key generation algorithm provides a private along with its corresponding public key. The signing algorithm produces a signature upon receiving a private key and the message that is being signed. Verification algorithm checks for the authenticity of the message by verify it along with the signature and public key.

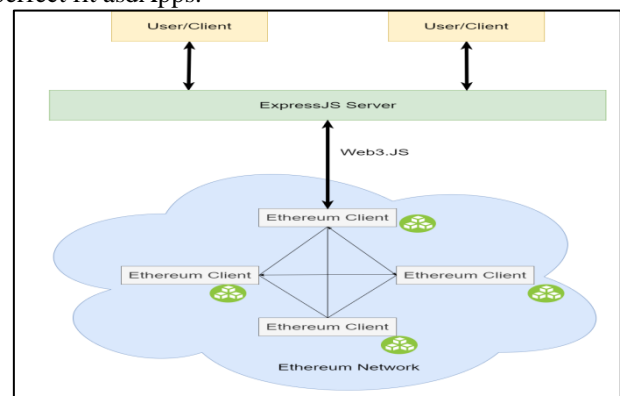

To produce new blocks to the chain and confirm transactions the consensus algorithm Proof of Work (PoW) is used. Miners will be at a competition for finding the solution for complex computational puzzles if one of them finds the solution to the new block all others will verify it. Work done by the miner will be present in the validated block that contains a block hash.

IV. SMART CONTRACTS

“Metamask is a bridge that allows you to visit the distributed web of tomorrow in your browser today. It allows you to run Ethereum DApps right in your browser without running a full Ethereum node” is what they say in their official website <https://metamask.io>, Most of the things that’s on the browser (e.g., Chrome, Firefox or Opera.), comes from a computer that sits in a chilled room within a large data center somewhere. Many little computers and phones, which often call clients, connect to the large central server to download bits of information that they need. This is

how the modern web works. It’s called as the Centralized Web, because it’s where all the data sits somewhere in a central location. However, some groups of people thought that having one large entity that stores, manages and even owns data is not very comfortable and often not safe. Instead, people decided to build a network where everyone can own and share a bit of data with everyone else in the network. So, instead of computers and phones connecting to a single server to download bits of information they need, they connect too many people who own smaller bits of information they need. And once they receive the information, they also begin to share it with others who need the same information. This is called as the Distributed Web. There have been many famous applications of distributed web. The two most wellknown examples are Napster and Torrent. Napster is a distributed web specifically built to share songs between its users. It has no central server that stores the songs, and users download and upload songs that they want and that they own. Similarly, Torrent is a distributed web specifically built to share all types of files between its users. Blockchain essentially is a distributed web, similar to Napster or Torrent, built to serve a different purpose. Blockchain is not a coin or some currency. It actually is a distributed web to log, store and share secure, verified and unmodifiable transactions. These transactions can include any type of actions between two entities. For example, in the case of bitcoin, transferring bitcoin between user A and user B can be stored in a blockchain. As you can see blockchain can store and share any type of data that needs security. Bitcoin is basically one application of blockchain technology.

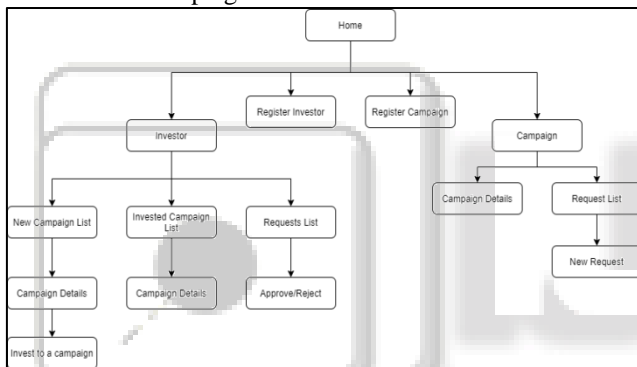

Ethereum is a type of blockchain that is built for applications that need to store data or run programs in the distributed web. It is the “distributed web of tomorrow”. Unlike bitcoin, Napster or Torrent, it can actually store data in the form of a computer program called smart contract. Computer owners can be part of the Ethereum network, obtain and share the smart contract and receive reward (Ethers) for running the smart contract. Once your computer is part of the Ethereum network, running smart contracts and sharing it with others, it is now an Ethereum Node. Ethereum allows programmers to write apps that can run on many people’s computers. Such type of apps are called DApps, which stands for distributed applications. DApps are being built every day and it is slowly gaining more traction. So, it will soon find out what type of applications are a perfect fit as DApps.

V. IMPLEMENTATION

This modern crowdfunding model is generally based on three types of actors: the project initiator who proposes the idea or project to be funded, individuals or groups who support the idea, and a moderating organization that brings the parties together to launch the idea.

Smart contract is implemented by using the solidity language. In the proposed system, the campaign creators will post their project ideas in the application and the interested people will donate the fund for the project idea. Where it differs from the old crowd funding system is that all the money is now converted into digital currencies like ether. All digital transactions using ether coin will be recorded and kept tracks in the block chain. This record stored in blocks cannot be changed since block chain is an immutable ledger. The Donor has control over the funded money. With the Request approval module, the donor has full control over the money they invested. Only fifty-one percentages i.e. more than half of the investors need to approve the request made by the creators. The investors trust over the campaign is improved by giving the money control to them which in turn improves transparency between the investors and campaign creators.

VI. CONCLUSION

Blockchain in crowdfunding is a relatively new concept to the community. We have taken that into consideration and designed this app so that even a common man can use it with ease. But this is not the end. With the evolution of Blockchain and introducing of ICOs, our application has a bright future and a large scope for improvement and evolution. The world is still adjusting to Blockchain and Cryptocurrencies and it'll take a couple of years more for Ethereum based Dapps to become popular and to be recognized by the community. In such a situation Blockchain based crowdfunding application is a tough concept to be understood by everyone. We have taken that into consideration and designed this app so that even a common man can use it with ease. But this is not the end. With the evolution of Blockchain and introducing of ICOs, our application has a bright future and a large scope for improvement and evolution.

Characterization of D-Gun Coated YSZ+Mullite Mixture

Dhanesh S¹

¹Assistant Professor –Mechanical Engineering, Ahalia School of Engineering and Technology
dhanesh1988[at]gmail.com

Abstract: *This work involves study about thermal barrier coatings and the need for thermal barrier coatings in IC engines. Study was made on different materials which are in use for thermal barrier coating along with its effect on improving the performance of the engine. Based on the study about the coating materials, suitable materials were selected which can be used for thermal barrier coating in IC engines. Mullite+YSZ in the ratio of 80/20 was coated using D-Gun with different set of operating parameters. The process parameters were first optimized for the coating of the chosen materials. Material characterization of the coated specimen involve the morphological analysis and hardness*

Keywords: D-Gun Coating, Mullite+YSZ, Characterization, Process Parameter, Thermal Barried Coating, hardness, morphology

1. Introduction

Thermal barrier coatings (TBC) are extensively used in areas of higher temperature like those of gas turbines and IC engines. A TBC system consists of a top coat and a bondcoat. The top coat provides thermal insulation to substrate and withstands large temperature gradients while the bond coat provides oxidation resistance along with an adhesion of the top coat to the substrate. Thermal spraying methods are used for the coating of the top coat and bond coat [1]. Plasma spraying and electron beam physical vapor deposition may be used. Even though plasma spraying can lead to a low thermal conductivity owing to the porosity and lamellar structure it does have the drawbacks of unmelted particles and defective microstructures within the coatings which may result in TBC delamination and spallation [3].

D-gun spraying is characterized by spraying of particles which are accelerated by detonation wave and impact on the substrate to be coated with high velocity of 800-1200m/s [4]. The high particle velocity produces a uniform and dense coating with a high hardness and good adhesion to substrate which gives a good coating performance.

Mullite (3Al₂O₃.2SiO₂) is an important ceramic material which can be used for TBC applications. It do posses the advantages of low density, high thermal stability, low thermal conductivity and favorable strength and creep behavior. It has been seen that compared with YSZ, mullite do have a much lower thermal expansion coefficient and higher thermal conductivity and better oxygen resistance than YSZ. In application like in diesel engines where surface temperatures are lower than that encountered in gas turbines and where temperature variations across coatings are large, mullite is an excellent alternative to YSZ. However but at a temperature of above 1273K the thermal cycling life of mullite is found to be inferior to that of YSZ. Cystrallization too happens in mullite at 1023-1273K which is accompanied by volume contraction causing in cracking and de-bonding [2].

YSZ is found to have a higher thermal coefficient of expansion and a lower thermal conductivity than that of

mullite [5]. A composite thermal barrier coating made of mullite and YSZ is found to have a better creep resistance along with the improvement in the thermal cycling life.

The objective of this work is to coat a composite mixture of mullite and YSZ in the ratio of 80:20 using D-gun and to study about the changes in the microstructure, hardness and find the optimum process parameter based on the results obtained.

2. Procedure

The Detonation gun basically consists of a long water cooled barrel with inlet valves for gases and powder. Oxygen and fuel (acetylene most common) is fed into the barrel along with a charge of powder. A spark is used to ignite the gas mixture and the resulting detonation heats and accelerates the powder to supersonic velocity down the barrel. A pulse of nitrogen is used to purge the barrel after each detonation. This process is repeated many times a second. The high kinetic energy of the hot powder particles on impact with the substrate results in a buildup of very dense and strong coatings.

The mixture of mullite and YSZ in the ratio of 80/20 is prepared by mixing the powders in ball milling machine continuously for two hours containing zirconia balls.

Before coating of the powders, the specimens are first grid blasted using sand blasting. The specimens to be coated for optimization of parameters are then fixed onto a holder and the coating is carried out.

Depending upon the powder to be coated the parameters chosen for coating varies. Oxygen is the one which controls the combustion process taking place and acetylene controls the flame velocity. Nitrogen acts as a carrier gas. The flame is that of neutralizing with oxygen to acetylene ratio remaining constant in all the parameters considered for the optimization of the parameters for coating.

The sample generated for thermal cycling test is coated on superalloyinconel. The coating consists of a bond coat of NiCrAlY which act as a adherent to the top coat. The bond

coat thickness was in the range of $75 \pm 100 \mu\text{m}$ and the top coat thickness was in the range of $100 \mu\text{m}$. The coated sample is then made to undergo thermal cycling to test for its thermal shock resistance.

3. Characterization

The coated specimens are characterized for different characteristics such as morphology, hardness and porosity [1]. Based on the characterization studies being carried out on the coated specimens the optimization process parameters is made for the coating of the powders on the piston and cylinder head. The specimens to be coated are first grid blasted using sand blasting. The sand blasted specimens are then fixed on the holder. The specimens are then coated using three different set of parameter keeping the ratio of oxygen to acetylene as constant.

The coated specimens are then cut using ISOMET 1000 which is a precision sectioning saw designed for cutting various types of materials of materials with minimal deformation. The cut specimen is then hot mounted using ISOMET hot mounting press apparatus. The specimen is kept for mounting for time duration of 20 minutes.

The mounted specimen is then polished using sand papers of different sizes ranging from 800 to 4000 in a systematic and sequential manner till the specimen gets mirror polish. The final polishing of the coated specimen is done using diamond polish with sizes of $3 \mu\text{m}$, $1 \mu\text{m}$ and $1/2 \mu\text{m}$. The finely polished specimens are then analyzed for morphology, hardness and porosity. Microstructural analysis of such finely polished specimens was carried out using scanning electron microscope. The hardness was tested using Viker Hardness Testing and the thermal cycling was carried out to study about the thermal resistance of the coated specimen.

4. Results and Discussion

The specimen of Mullite+YSZ was coated using the parameters shown in table 1

Table 1: List of Operating Parameters

Parameter	O2(lph)	C2H2(lph)	N2(lph)	Spraying Distance (mm)
1	4800	1720	720	200
2	5040	1920	720	200
3	5040	2240	720	200

Figure 1 shows the microstructure obtained using first set of operating parameter.

Figure 1: SEM Image of Parameter 1

The SEM analysis shows the coating using 1st parameter was uniform with proper flow if mixture of mullite and YSZ.

Figure 2 shows the EDS analysis of the specimen coated using 1st parameter of mullite + YSZ.

Figure 2: EDS Analysis for Parameter 1

EDS analysis shows that the percentage of mullite and YSZ was in accordance with the percentage of the materials being mixed.

Figure 3 shows the image analysis of specimen coated using 2nd parameter of mixture of mullite + YSZ

Figure 3: SEM Image for Parameter 2

The SEM image shows that the coating was uniform. But vertical cracks were found to develop in the coating which is not favored.

Figure 4.13 shows the EDS analysis of coating of specimen using 3rd parameter of mullite + YSZ

The EDS analysis shows the percentage of mullite and zirconia was found in accordance with the mixing proportion. While white flows correspond to the YSZ, the black one corresponds to that of mullite.

Figure 4: EDS Analysis for Parameter 2

Figure 5 shows the image analysis of specimen coating using 3rd parameter of mullite + YSZ

Figure 5: SEM Image for Parameter 3

The SEM analysis shows that, the coatings have developed vertical cracks as well as horizontal cracks.

Figure 6 shows the EDS analysis of the coated specimen using 3rd parameter of mullite + YSZ

Figure 6: EDS Analysis for Parameter 3

Table 2: Hardness Value for Different Parameters

Parameter	Average	Maximum	Minimum	Std. Deviation	No. of Indentations
1	656HV 0.2	710HV 0.2	608HV 0.2	40.2	10
2	701HV 0.2	799HV 0.2	608HV 0.2	62.43	10
3	1114HV 0.2	1268HV 0.2	956HV 0.2	95.86	10

The hardness values shows that the hardness was maximum for coating using 3rd parameters but with greater deviation in the values. The hardness of coating using 1st parameter was found to be least but with lesser deviation in the hardness values.

5. Conclusion

Based on the study carried out the following observations were made.

1. Mullite+YSZ was coated in the proportion of 20:80 using D-Gun coating using three different set of process parameters.
2. The characterization study was carried out so as to find the optimum set of process parameters for coating.
3. Microstructural analysis and hardness measurement was carried out.
4. Based on the results obtained, it was observed that first parameter for coating would result in optimum coating.

Student, Electronics and Communication Engineering, Ahalia School of Engineering & Technology, Kerala, India³

Abstract: Irrigation is need of farmer to save water resource and need to use in minimum quantity because it is not a conversational resource. Agricultural sector uses maximum water in world. Due to its immense use water is vanishing day by day. Irrigation is one solution to this problem as it saves large amount of water. In traditional irrigation method water is sometimes over supplied or less supplied to the crop. So it is hard to take a decision to save water and get maximum profit from the field. This traditional method requires manual intervention. It creates a need of more labor work and maintenance. Thus maintaining a good irrigation system is a necessity in today's water scarcity environment. Hence a new system which makes the irrigation fully automated is being proposed. In our proposed automated system the temperature of irrigation field is being measured by a temperature sensor and based on the sensed value the crops is being watered. This whole system works all the time without any interruption in the working of our proposed system using uninterruptable power supply.

I. INTRODUCTION

Agriculture is considered as the main source of income in India. This is an important factor in human society to growing demand in food production. But agricultural areas are getting reduced due to laziness in mankind. In past farmers depend on monsoon for cultivation. Thus they suffered a lot due to lack irrigation. Irrigation is defined as the science of artificial application of water to the crops. But the irrigation system which is of current technology is time consuming one and also requires high maintenance. Today farmers face the problem of unavailability of sufficient water for irrigation. Thus we can say efficient management of water resources plays a crucial role in agricultural sector. In our country most of the irrigation systems are operated manually. This unmanned system adversely affects the growth of crops.

Our system comprises some changes in usual irrigation system. The proposed automated irrigation system, contrary to a traditional irrigation method regulates supplied water automatically to the field based on the temperature in the irrigation field. We use sensors to acquire the corresponding data.

The requirement of multiple sensors spread out over the field means the presence of many wires in it. This will create a lot of problems in ploughing, harvesting etc. Wireless connectivity to the sensor is a best idea in this context. Thus the sensor data is sent through Xbee; a low

cost wireless communication modules to microcontroller which then regulates the water supply. The whole system efficiently operates with UPS which protects our sophisticated devices from sudden power supply failure and supply variations.

Automating irrigation allows farmers to apply right amount of water at the right time, regardless of availability of the labors. If the plants get water at the proper time then its production can be increased up to 30%. Thus through this system we are modernizing agriculture sector, thereby conserving water resources, increasing production, save energy of the farmer.

Many features can be further be added to this like a system to identify the insects in crops and pesticides is sprayed only in that portion using a stream video camera through image processing.

II. TRADITIONAL METHODS OF IRRIGATION

The water available in wells, lakes and canals is lifted up by different methods in different regions, for taking it to the fields. Cattle and human labor is used in these methods. So these methods are cheaper, but less efficient. The various traditional ways are

Moat (Pulley system): A moat or pulley system of irrigation is one that involves pulling water up from a well

or other water source in order to water plants and other crops. It is not often in use as it can be time consuming and may not always be as efficient as other methods of irrigation. On the other hand, it does not cost a lot of money to install a moat or pulley irrigation system as it does not require vast technology or machinery invested in it

Fig. 1: Moat (pulley system)

Chain pump: These ancient Chinese irrigation systems use round metal discs and a long loop of metal chain to water soil and plants. Each metal disc runs through a pool of liquid, and each disc collects some water during this process. When the chain is pulled, the metal disc rises up to the top, and the water held inside pours out, hydrating the earth and flora. This low-cost method of traditional irrigation has been practiced for centuries.

Fig. 2: Chain pump

III. MODERN METHODS OF IRRIGATION

Sprinkler System: This system is more useful on the uneven land where water is available in smaller quantity. The perpendicular pipes, having rotating nozzles on the top, are joined to the main pipeline at regular intervals. When the water is allowed to flow through the main pipe with the help of a pump, it escapes from the rotating nozzles. It is sprinkled on the crop as if it is raining. Sprinkler is very useful for the sandy soil

Fig. 3: Sprinkler system

Drip System: In this system, the water falls drop by drop just at the position of the roots. So it is called drip system. It is the best technique of watering fruit plants, gardens and trees. This system consists of a main pipe to which lateral pipes are joined. The specially prepared nozzles are attached to these lateral pipes to water plants drop by drop. Water is not wasted at all. So, it is a boon in regions where availability of water is poor.

Fig. 4: Drip irrigation system

IV. METHODOLOGY

The outmoded irrigation technique has been replaced with automated technique. Many smart irrigation systems have been devised. A smart irrigation system, contrary to a traditional irrigation method, regulates supplied water according to the needs of the fields and crops. The feedback mechanism of a smart irrigation system is a temperature sensor. This temperature sensor is placed at a specific location on the irrigation field. Based on its value the water is being pumped to corresponding area up to a predetermined time. Wireless communication technology will make the communication possible between transmitter section and receiver section. This will avoid the presence of many wires in the field. Otherwise it may create a lot of problems to ploughing, harvesting, etc.

V. PROPOSED BLOCK DIAGRAM

The proposed block diagram of our system mainly consist of Arduino, Temperature sensor, XBEE, Relay, Valve, Pump and UPS. The temperature from the atmosphere is measured. The temperature sensor used is LM35. The LM35 is precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius temperature. The LM35 is operates at -55° to +120°

LM35 has three terminals and required Maximum of 5.5 V supply. This type of sensor consists of a material that performs the operation according to temperature to vary the resistance. This change of resistance is sensed by circuit and it calculates temperature.

Temperature sensors directly connected to microprocessor input and thus capable of direct and reliable communication with microprocessors. The sensor unit can communicate effectively with low-cost direct and reliable communication with microprocessors. The temperature sensor unit can communicate effectively with low-cost processors without the need of A/D converters.

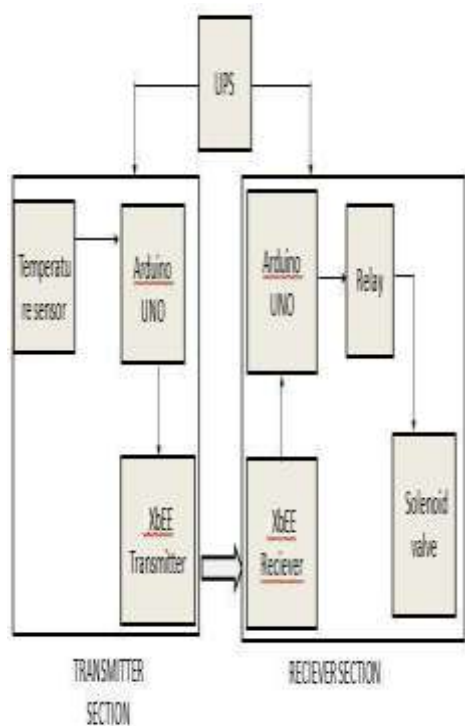

Fig. Block diagram

The output is then given to XBEE module for wireless transmission to base station. The XBEE RF modules were engineered to meet IEEE 802.15.4 standards and support the unique needs of low cost, low power wireless sensor networks, the module require minimal power and provide reliable delivery of data between devices. The module

operates within 2.4MHz frequency band with a data transfer rate of 250kbps and it allows point to point, point to multipoint and mesh networking methods.

The data from XBEE router is received at the receiver side by the XBEE coordinator and this data is transferred to Arduino board.

The ARDUINO UNO is one of the most common and widely used Arduino processor boards. This is a microcontroller based on ATmega328P. It has digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, USB connection, a power jack and a reset button.

It contains everything needed to support the microcontroller; simply connect it to a battery to get started.

If the temperature is above threshold value, then the Arduino pass information to the relay for the opening of the solenoid valve and the water is pumped to the field through pump to the agriculture field.

If the temperature reaches below threshold value, then the Arduino provide information hence relay control the closing of the solenoid valve. Relays are simple switches which are operated both electrically and mechanically. Relays consist of an electromagnet and also a set of contacts. The switching mechanism is carried out with the help of the electromagnet.

The relay is used to connect and disconnect the load from the main power. An Uninterrupted Power Supply is employed along with the system to provide adequate power for the working of the entire system.

Power supply system

An UPS is the central component of any well-designed power protection architecture. A static UPS is designed to be the prime source of power to a every critical load. A UPS not only provides uninterruptible power to a critical load, but also isolation from the utility fine and the associated fine voltage variations as well as various forms of voltage transients present on the utility line. The method in which one or more UPS units are utilized will dictate the cost of the system and the degree of load protection provided by the system.

In this system, 230V supply is stepped down to 12V AC. This is then converted into 12V DC with the help of rectifiers, capacitors and regulators. This 12V DC is used to charge a battery and output of the battery is given to our smart irrigation system. Thus our system becomes independent of power supply variations and supply failures. The experimental setup of following is given below.

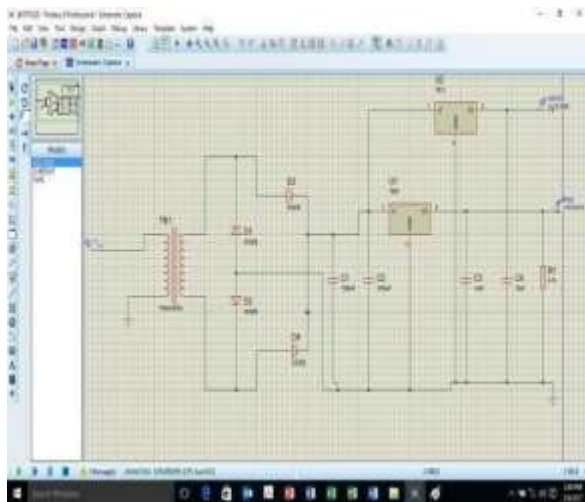

Fig. Power supply simulated in proteus 7

VI. CONCLUSION AND FUTURE SCOPE

Our proposed automated irrigation system requires less man power for operation. The water is been supplied by the field only when the soil humidity goes below the reference level. The system helps minimizing the overall watering and crops production cost. This system is considered to be cost effective and cultivation of agricultural products and plants in the area where there is water scarcity. It requires very less maintenance and is adjustable according to the changing environment. Through this system we can step in to an unmanned irrigation, which is highly efficient. Automated irrigation system has huge demand and future scope too. This system can also supply fertilizer and other agricultural chemicals like calcium, sodium, ammonium, and zinc to the field by adding new sensors and valves.

Many features can further be added to this system which definitely includes web-based communication, mobile alerts and weather adaptive systems. This type of system is a good solution for condition monitoring of agricultural setups as it is very low in cost. This idea should be implemented to large scale farms in the form of sensor grids in which each sensor will be treated as a Zig Bee node.

Additional feature to identify the insects in crops and pesticides sprayed only in that portion using the stream video camera through image processing can also be included. Proposed system can also be modified and used in such a way that it can sense the water level of the tank and whenever this water level is too low then the system can immediately provide a sound alarm, then it automatically switch on the motor. When the water level reaches 90% of the tank then the motor can be switched off through remote system. This automated system can be used in cricket stadium, golf stadium.

ACKNOWLEDGEMNT

We would like to express our sincere gratitude to **Prof. Dr. B. G. VISHNURAM**, the Honorable Principal for his timely support extended throughout the project.

We would like to express our sincere thanks to our beloved HOD **Prof. Dr. V. BALAMURUGAN** for his sincere help and guidance through the project. We would like to express our heartfelt thanks to our project guide **Mr. Sujith P. S.** for his guidance and motivation.

Any project would not be successful if it does not rely on the reference material. In this context we wish to express profound sense of gratitude to all teaching and non-teaching staff of our college for giving us a supportive environment in the college.

Abstract:

In this paper, we propose a new technique for implementing a half adder circuit consisting of minimum number of transistors (3-T). The W/L ratio is varied to get the required output. An adder is a digital circuit that performs addition of two numbers. In many computers and other kind of processors, adders are used not only in arithmetic logic unit but also in other parts of the processors where they are used to calculate addresses, table indices and similar operations. Simulated results indicate the performance of proposed half adder over the conventional half adders. Detailed comparison of the simulated results is presented here which is done in MultiSim software.

Keywords: Pass Transistor Logic, 3-T XOR, Logical Effort and Transistor Sizing

I. INTRODUCTION

Since the introduction of integrated circuits decades ago methods to speed up digital circuits and to reduce the area of their designs have great importance. The power dissipation per unit area grows as the number of transistors per chip increases which also increases the chip temperature. This excessive temperature reduces the reliability and lifetime of the circuit.

The CMOS technology has a great influence in the performance of microprocessors. Dynamic CMOS circuits are used in microprocessors to improve their timing performance. This method has many challenges like transistor sizing, charge sharing, noise-immunity, leakage current etc.

The growing world demands for circuits with ultra-low power dissipation. The presence of complementary transistors avoids contention. It ensures that if the inputs are not changing then there is no power dissipation. Here the output voltage level is connected to the power or ground line or both.

Various techniques have been implemented to reduce power dissipation at circuit, architectural and system level. The number of gates per chip area is constantly increasing, while the gate switching energy does not decrease at the same rate, so power dissipation rises and heat removal becomes difficult

and expensive. The proposed thesis is to develop a hybrid VLSI circuit that improves the circuit performance by reducing the number of transistors. The output of the gate can be improved by changing the W/L ratio of the transistor. The points to be noted while changing the W/L ratio:

1. As W/L increases the drain-to source current increases.
2. As W/L ratio increases the response time increases.
3. W/L ratio is roughly proportional to the resistance.
4. The W/L ratio of PMOS should be larger than the NMOS.
5. Make the MOSFET in the output side the largest.

Logical effort is a method to make certain decisions:

1. Uses a simple model of delay.
2. Allows back of the envelope calculations.
3. Helps make rapid comparison between comparatives.
4. Emphasises remarkable symmetries.

In electronics, an adder or summer is a digital circuit that performs addition of numbers. In modern computers adders reside in Arithmetic logic unit (ALU) where other operations are performed. Although adders can be constructed for many numerical representations, such as Binary coded decimal or excess-3, the most common adders operate on binary numbers. In cases where two's complement or one's complement is being used to represent negative numbers, it is trivial to modify an adder into an adder-subtractor. Other signed number representations require a more complex adder.

In [1] the authors have designed a low power high speed multiplier using full adder consisting of minimum no. of transistors in which they modified the blocks AND gate and the XOR gate the idea behind this work is utilized here. Recently many techniques have been proposed with the objective of improving speed and power consumption [2], [3].

Paper is organized as follows. Section II describes the related work. Section III describes the proposed system. Section IV shows the simulation results.

II. RELATED WORK

Half adder is a combinational arithmetic circuit. A half adder adds two one-bit binary

numbers A and B. The input variables of a half adder are called the augend and addend bits. It has two outputs, S and C which is the sum and carry respectively. Carry is the output which is carried into the next stages. The simplest half adder design pictured incorporates an XOR gate for S and an AND gate for C. If A and B are the input bits, the sum bit(S) is the X-OR of A and B and the carry bit(C) will be the AND of A and B. Half adder is the simplest of all circuit. The inputs to the XOR gates are also inputs to the AND gate. The input “wires” to the XOR gate are tied to the input wires of AND gate. Thus, when voltage is applied to the A input of the XOR gate, the A input to the AND gate receives the same voltage. The Half adder can add only two bits so if input to a half adder have a carry then it will be neglected and adds only the A and B bits which means that the binary addition process is not complete and that’s why it is called a Half adder.

- 0+0 = Sum 0 Carry 0
- 0+1 = Sum 1 Carry 0
- 1+0 = Sum 1 Carry 0
- 1+1 = Sum 0 Carry 1

0	1	1	0
1	0	1	0
1	1	0	1

The previous work presents adder circuits using pass transistor logic based MUX & XOR gate, which contains lesser no. of transistors. The pass transistor logic reduces the count of transistors used to make different logic circuits, by eliminating redundant transistors. Transistors are used as switches to pass logic levels between nodes of a circuit voltage[4]. This reduces the number of active devices, but has the disadvantage that output levels can be no higher than the input level. Each transistor in series has a lower voltage at its output than at its input [5]. For proper operation, design [6].

Figure 3:3-T XOR

Pass transistor logic has become important for the design of low-power high-performance digital circuits due to the smaller node capacitances and reduced transistors count it offers. The 5-T half adder was designed using this 3-T XOR and 2-T AND gate.

Figure 4:2-T MUX

A 2-T MUX is used as an AND gate. The input A is given to the select line. The output depends on the value given to A. When A=0 output is 0 since the MUX is off. When A=1 the value given to B is obtained as output. Hence the conditions for AND gate is satisfied.

III. PROPOSED SYSTEM

The three major sources of power dissipation in a digital CMOS circuit are logic transition, short-circuit current and leakage current. The short-circuit current is the direct current passing through the supply and the ground, when both the NMOS and the PMOS transistors are simultaneously active. The proposed half adder is of 3T which is a variation from the existing half adder. The XOR gate itself can be used as a half adder. In the figure below the transistors M1 and M2 forms an inverter circuit. The CMOS inverter output is at high impedance when input B is at logic low and when B

is at logic high the inverter acts like a normal inverter .when input B is at logic low the pass transistor M3 is enabled and the output S gets the same logic value as input A. Now when A=1 and B=0, due to threshold drop voltage degradation occurs across transistor M3 and consequently the output S is degraded with respect to the input. The voltage degradation due to threshold drop can be considerably minimized by increasing the W/L ratio of transistor M3. The desired output is obtained by varying the W/L ratio. The sum is obtained from the M3 transistor and Carry is obtained across its drain and source.

Since the proposed circuit has only 3 transistors it reduces the chip area and thereby reduces power consumption.

Figure 5:3-T Half Adder

IV. EXPERIMENTAL RESULTS

Figures show the simulation results of the proposed half adder. Simulation is done in Multisim software. The connections are made as in the circuit. A 5V represents logic 1 and a 0V represents logic 0. The two inputs are A: (S1), B:(S2). The output of the half adder the sum(S) and the carry(C) is connected to the oscilloscope. The red line represents the sum and pink line represents the carry in the graph. Figure 6, figure 7, figure 8, figure 9 shows the graph for various input combinations 00,01,10,11 respectively and Table 2 shows the output values of these input combinations. From the table it is clear that the proposed half adder shows a result which is more feasible compared to a conventional half adder.

Table 3: Output of Conventional and Proposed Half Adder

Combinations	5-T Half Adder		3-T Half Adder	
	Sum	Carry	Sum	Carry
00	0V	0 V	0 V	0 V
01	3.07 V	1.366 V	4.49 V	504.73mV
10	3.09 V	-174.82mV	4.37 V	-155.41mV
11	100 nV	4.99 V	1.0u V	4.96 V

V. CONCLUSION

A 3-T half adder by varying the W/L ratio to obtain the desired output has been implemented. The proposed circuit can be used where low power consumption is an essential requirement like in design of high-speed embedded processors. A reduction in power consumption provides several benefits. As a future scope of the work, Power of circuit can be further reduced by sizing the transistor keeping logical effort in mind.

Design of Interlocking Block and Replacement of Msand by Concrete Roof Tile Waste

I.P.Malavika¹, Nipuna.M², Raina T. R³, Sreelakshmi A.V⁴, Kripa K.M⁵

^{1,2,3,4} Students Dept. of Civil Engineering, Ahalia school of Engineering and Technology, Kerala, India

⁵Assistant Professor, Dept. of Civil Engineering, Ahalia school of Engineering and Technology, Kerala, India

Abstract – Interlocking blocks are one of the alternatives for the conventional burnt clay brick. This report deals with the design of interlocking blocks and also replacement of the m-sand by concrete roof tile waste in various percentages and finding the optimum percentage of tile waste by testing the cubes casted for compressive strength of 3 days and finally casting the blocks with that optimum percentage of tile waste. The report finally gives the results of an experimental investigation in which the compressive strength, water absorption and density were investigated by using optimum percentage of tile waste, m- sand, cement and 6mm aggregate with mix proportion of 1:2:4. The experimental results are compared with that ordinary solid block. The results indicate that these blocks are slightly lighter in weight, durable in aggressive environments and have better strength for their use in building construction.

Key Words: Interlocking block, Roof tile waste, Replacement, Compressive strength

1. INTRODUCTION

The interlocking blocks are different from other normal bricks as it requires less mortar or cement for masonry work. These blocks interlocked with each other by means of positives and negative frogs on the top and bottom of the blocks which disallow the horizontal compressive stress and lateral movement of blocks. The projection of one block fits into the depression of the next so that they always align perfectly. The specifications and the characteristics of this block depend on the machine used to manufacture it. The most common size of block is 300x150x120mm. The basic raw materials are cement, fine aggregate and coarse aggregate. This is usually done with mechanized compaction and vibration.

Current process of producing the interlocking block is by using a semi mechanized stationary type machine. The other production systems are - manual mould that requires hand tamping, a mobile semi-mechanized egg-laying machine and fully mechanized system that combines compression and manual concrete filling in mould. The machine also compacts and consolidates the mix so that the blocks are uniform in size and attain desired physical properties.

The blocks are cured for a minimum period of 14 days, before they are ready to use. On an average 600-800 blocks can be made in 8 hours by 1 skilled and 6-8 semi-skilled

workers. There are various types of interlocking blocks. The most commonly used cement interlocking blocks are regular shaped block, half size block and u-shaped block.

1.1 Advantages of Interlocking Blocks

Interlocking blocks offer numerous advantages to other building materials. The materials required for production are widely available so they do not have to be shipped in from long distances. Since the manufacturing process is a simple one, production facilities can be easily set up at convenient geographical locations, once again reducing the cost of transporting them to the construction site. In the case of very large construction projects, an interlocking block production facility can be set up at the construction site to provide the most cost effective supply solution.

Without the need of high waged skilled masons, by saving cement and with the speed of construction, the building costs are lower than that for standard masonry construction. When compared to convention masonry block construction, interlocking blocks, which are dry assembled, save a great deal of mortar which is normally used for vertical and horizontal joints, which produces savings in terms of both cost and time. The structural stability and durability of interlocking block construction can be far greater than the normal construction.

2. DESIGN OF INTERLOCKING BLOCKS

Each blocks have two interlocks, a projection 'tongue' part and a depression 'groove' part, this helps to resist the lateral movements and horizontal compressive stresses caused due to earthquakes.

Size of the block is chosen to be 300 X 220 X150 (in mm) and width is of 220mm, it covers the total width of two normal bricks, therefore no need of plastering. It covers an area of about more than 3 normal bricks. Slopes are provided for the ease in interlocking between the blocks so that there will not be any problem in aligning the blocks. Height of the projection is about 2.5cm, therefore less amount of mortar needed. Slope is 1 in 2, therefore front view will be of pleasing nature. As well as less amount of mortar needed, if it is to be plastered. The blocks are shaped with projecting parts, which fit exactly into depressions in the blocks placed above, such that they are automatically aligned horizontally and vertically thus block laying is possible without special

masonry skills. Each block has a projection in one end of blocks side face and a depression in other end. Since the blocks can be laid dry, less mortar is required and a considerable amount of cement is saved.

Fig -1: CAD Drawing

Fig -2: Parts of mould

3. METHODOLOGY

In this methodology, the materials used were:-Cement (53 grade), M-Sand, Concrete roof tile waste (collected from "PIONEER ROOFING TILES" company), Coarse aggregate (6mm).

3.1. Trial Casting

In trial 1, mix design was done and the ratio obtained was 1:1.54:2.51. Since this ratio cannot be adopted according to clause 7.1.1 IS 2185 (Part 1):2005. Also we analyzed that the water content was not sufficient for providing workable mix. In trial 2, 4 cubes of size 15cm x 15cm were cast in the mix proportions of 1:2:4 and 1:3:6 using 53 grade cement, 6 mm coarse aggregate and M-sand. The cubes were tested for compression and the results obtained were:-
 Compressive strength of M15 mix cube =15 MPa
 Compressive strength of M10 mix cube =9 MPa
 The ratio of M15 mix cube was adopted and decided to add Master Glenium Sky 8233 for better finishing as well as for increasing workability.

Fig -3: Cubes of M10 and M15 mix

Slump test was done in the fixed ratio of 1:2:4 for finding the water-cement ratio and thus obtained the value as 0.45. In trial 3, 14 cubes of size 10cm x 10cm were cast in the ratio of 1:2:4 with the replacement of M-sand by roof tile wastes as 0%, 5%, 10%, 15%, 20%, 25% and 30%. The cubes were tested for compressive strength test.

Fig -4: Cast cubes by replacement of M sand by roof tile waste in 0,5,10,15,20,25 and 30%

Chart 1: Compressive strength of cubes and optimum value fixation

Since 20% replacement was the optimum value, concluded to cast the interlocking block with this ratio.

3.2. Casting of interlocking blocks

The blocks were cast in the ratio 1:2:4 by using 53 grade cement, Msand replaced by 20% of roof tile waste, 6mm aggregate. All the materials were mixed in the mould and compacted using vibratory compaction machine. 11 cubes

were casted and were tested for compressive strength, water absorption, and block density.

Fig -5: Interlocking block with mould

Fig -6: Interlocking blocks cast

4. TESTS AND RESULTS

4.1. Material Tests

Tests were conducted on the aggregates used and following results were obtained
 Specific gravity of cement = 2.92
 Specific gravity of tile waste = 2.262
 Specific gravity of Msand = 2.26
 Normal consistency of cement = 33%
 Fineness of cement = 4.6%
 Sieve analysis of Msand and tile wastes were done

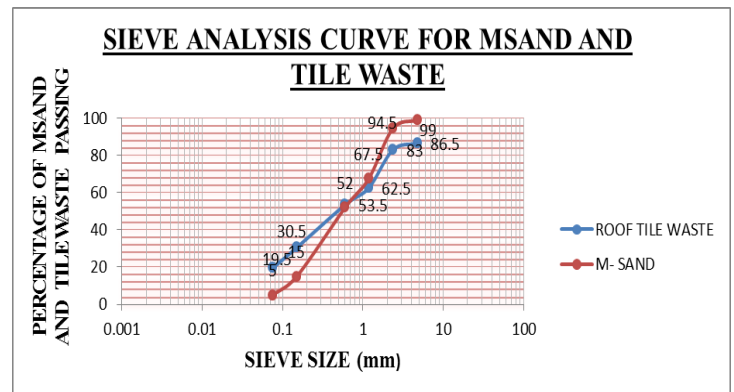

Chart 2: Particle size distribution for Msand and roof tile waste

4.2. Interlocking block tests

4.2.1. Water absorption

Table 1: Water absorption

WATER ABSORPTION		
	Wet mass (kg)	Dry mass (kg)
Specimen 1	18.820	18.500
Specimen 2	18.980	18.600
Concordant value	18.840	18.550

After 28 days continuous curing,

$$\text{Water absorption} = \frac{(18.84 - 18.55)}{(18.55)} \times 100 = 1.563.$$

It should not be more than 10 percent by mass.

$$10\% \text{ by mass} = 0.1 \times 18.21 = 1.821; 1.563 < 1.821.$$

It was safe as per code IS 2185 (PART 1): 2005.

4.2.2. Compressive strength

Specimen shall be tested only after the curing period of 28 days. The bearing surface of the testing shall be wiped clean and any loose material removed from the surface. Place the specimen in the compressive testing machine and keep the steel plates on the top and bottom of the specimen. Fill the gaps the between the specimen and the steel plates using sand. The load shall be applied slowly without shock and increased continuously until the resistance of the specimen to the increased load breaks down and no greater load can be sustained. The maximum load applied to the specimen shall then be recorded.

Table 2: Compressive strength

COMPRESSIVE STRENGTH		
	Crack load (kN)	Collapse load (kN)
Specimen 1	195	350
Specimen 2	205	350
Concordant value	200	350

Fig-8: Compressive strength value

Compressive strength of solid block = 2.05MPa. Therefore, when compared with solid block interlocking block is found to have greater compressive strength.

Crack load value=200 kN
 Collapse load value=350 kN
 Compressive strength of crack load =Load/Area
 = $(200 \times 10^3) / (660 \times 10^2) = 3.03 \text{MPa}$
 Compressive strength of collapse load =Load/Area
 = $(350 \times 10^3) / (660 \times 10^2) = 5.30 \text{MPa}$

Fig-7: Compressive strength set up

4.2.3. Block density

Table 3: Block density

BLOCK DENSITY		
	Mass (kg)	
	Before drying	After oven drying
Specimen 1	18.190	17.980
Specimen 2	18.230	17.960
Concordant value	18.210	17.980

Volume of the block=9900 cm³
 Density of block before drying = $(18.210/9900) \times 10^6 \text{ kg/m}^3$
 =1839 kg/m³
 Density of block after oven drying = $(17.980/9900) \times 10^6 \text{ kg/m}^3$
 =1816.1 kg/m³
 It was safe as per code IS 2185 (PART 1): 2005.

5. ESTIMATION

Comparison of cost estimation of Interlocking block with solid block

5.1. Cost Estimation of solid block (1m³)

5.1.1. Cost of 100 blocks

Cost of cement = Rs 1788.8
 Cost of Msand = Rs 536

Cost of coarse aggregate = Rs 2817.57
Total cost of solid block required for 1m³ wall =
Rs 5142.434

5.1.2. Mortar

Cost of mortar = Rs 338.638 (including plastering charge of 60%)

5.1.3. Labour cost

10% of the total cost.
Therefore, Total cost = Rs 6029.22

5.2. Cost estimation of interlocking blocks (1m³)

5.2.1 .Cost of 100 blocks

Cost of cement = Rs 2400
Cost of M-Sand = Rs 384
Cost of coarse aggregate = Rs 2520
Total cost of solid block required for 1m³ wall = Rs 5304

5.2.2. Mortar

Cost of mortar = Rs 16
1.5% of the total cost for architectural works
Therefore, Total cost = Rs 5406.10

5.2.3. Labour cost

When 10% of the total cost is considered, total cost = Rs 5946.71.

Since the amount of mortar required for construction is less as well as the aligning of interlocking block requires only a fair time, it requires half of the labour cost when considered with solid block. Therefore, assuming labour cost as 5% of total cost.

Total cost = Rs 5676.405

Percentage of saving = 5.85%

Thus, it can make a large variation in the cost estimation of a building

6. CONCLUSIONS

Depending upon certain considerations, a suitable interlocking block has been designed. Interlocking blocks were cast successfully as per the code 2185:2005 (part 1) in the mould made of mild steel.

1. Optimum value of Msand by tile waste replacement was found as 20% through trials. Block density and water absorption tests were satisfactory.

2. Compressive strength of interlocking block was found greater than that of ordinary solid block of approximately same size and components. Compressive strength of interlocking block and solid block obtained were 5.45MPa and 2.05MPa respectively.

3. Comparison of cost analysis of interlocking block with solid block resulted in an economic construction. Rate of construction for 1m³ using solid block and interlocking block were obtained as Rs 6029.22 and Rs 5676.40 respectively.

4. Because of the pattern of interlock, it provides better matrix strengthening, wall stability, disallows movements and reduces mortar.

Therefore, the interlocking block masonry can be adopted as a suitable substitute for traditional masonry. And in conclusion, interlocking masonry can be recommended for housing projects as an alternative method that is cheaper than the conventional.

Abstract- The explosive growth of battery operated portable applications such as cellular phones, smart cards, PDAs, laptops and the evolution of the shrinkage of the technology requires smaller silicon area, high throughput circuitry and most importantly low power. Power consumption of any system can be reduced by scaling the supply voltage and operating frequency. But, it increases the propagation delay of the system and degrades the driving capability of the design. Therefore, designing a full adder with improved power delay characteristics is of great interest. The greatest challenge in low power VLSI design is reduction of power dissipation. Novel circuits for XOR/XNOR and simultaneous XOR-XNOR functions are proposed. The proposed circuits are highly optimized in terms of the power consumption. The proposed circuits are investigated in terms of variations of the supply and threshold voltages, output capacitance, input noise immunity, and the size of transistors. The simulations are carried out in Tanner EDA tool.

Key Words: CMOS, Low power VLSI, Full Adder, XOR-XNOR, Tanner EDA, Virtual ground.

1. INTRODUCTION

TODAY, ubiquitous electronic systems are an inseparable part of everyday life. Digital circuits, e.g., microprocessors, digital communication devices, and digital signal processors, comprise a large part of electronic systems. As

the scale of integration increases, the usability of circuits is restricted by the augmenting amounts of power and area consumption. Therefore, with the growing popularity and demand for the battery-operated portable devices such as mobile phones, tablets, and laptops, the designers try to reduce power consumption and area of such systems while preserving speed. Optimizing the W/L ratio of transistors is one approach to decrease the power-delay product (PDP) of the circuit while preventing the problems resulted from reducing the supply voltage. The efficiency of many digital applications appertains to the performance of the arithmetic circuits, such as adders, multipliers, and dividers. Due to the fundamental role of addition in all the arithmetic operations, many efforts have been made to explore efficient adder structures, e.g., carry select, carry skip, conditional sum, and carry look-ahead adders. Full adder (FA) as the fundamental block of these structures is at the center of attention. Based on the output voltage level, FA circuits can be divided into full-swing and non full-swing categories. Standard CMOS complementary pass transistor logic (CPL) transmission gate (TG) transmission function 14T (14 transistors), 16T and hybrid pass logic with static CMOS output drive full adder (HPSC). FAs are the most important full-swing families. Non full-swing category comprises of 10T, 9T, and 8T.

In this paper, we evaluate several circuits for the XOR or XNOR (XOR/XNOR) and simultaneous XOR and XNOR (XOR-XNOR) gates and offer new circuits for each of them. Also, we try to remove the problems existing in the investigated circuits.

Afterward, with these new XOR/XNOR and XOR-XNOR circuits, we propose six new FA structures. The circuits for XOR/XNOR and simultaneous XOR-XNOR are reviewed, novel XOR/XNOR and XOR-XNOR circuits are proposed and the

simulation results of these structures are presented. In the transistor sizing methods are first investigated and the circuits are simulated for power, delay, and PDP parameters. The simulation results are analyzed and compared.

2 PROPOSED DESIGN

In this paper the circuits are designed using novel XOR-XNOR circuit. One of the important factors is that excessive power consumption is becoming the limiting factor in integrating more transistors on a single chip or on a multichip module. Unless power consumption is dramatically reduced, the resulting heat will limit the feasible packing and performance of VLSI circuits and systems. So XOR-XNOR circuit is in-cooperated in digital circuits to reduce the power consumption.

2.1 INVERTER

An inverter circuit outputs a voltage representing the opposite logic-level to its input. Inverters can be constructed using two complementary transistors in a CMOS configuration. This configuration greatly reduces power consumption since one of the transistors is always off in both logic states.

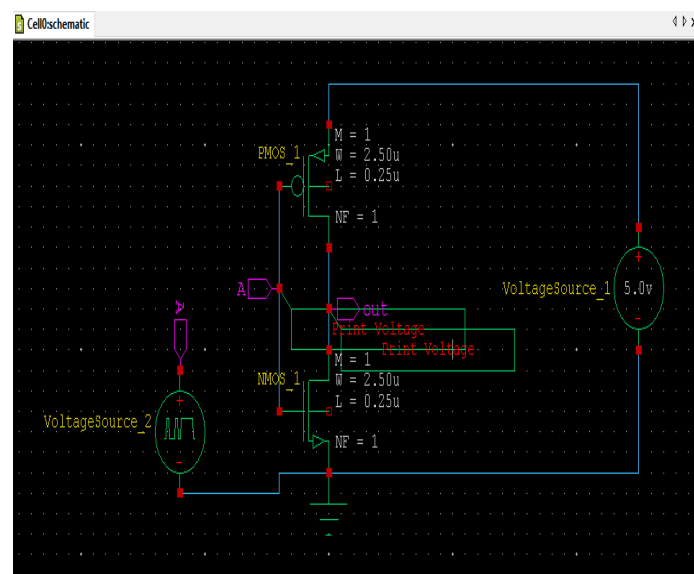

Fig-1: Inverter circuit

The proposed XOR and XNOR circuits are based on the modified version of a CMOS inverter and pass transistor logic. In proposed circuit-I, for XOR when the input B is at logic 1, the inverter circuit functions like a

normal CMOS inverter. Therefore, the output is the complement of input A.

2.2 CMOS HALF ADDER

Adders are used in processors in the arithmetic logic units, to calculate addresses, table indices, and other similar operations. A fast and energy-efficient adder plays a vital role in electronics industry. Adder contributes substantially to the total power consumption of the system. Half Adders are frequently required in VLSI from processors to application specific integrated circuits (ASICs). Adder circuit is a combinational digital circuit that is used for adding two numbers. A typical adder circuit produces a sum bit (denoted by S) and a carry bit (denoted by C) as the output. Typically adders are realized for adding binary numbers but they can be also realized for adding other formats like BCD (binary coded decimal, XS-3 etc. Besides addition, adder circuits can be used for a lot of other applications in digital electronics like address decoding, table index calculation etc. For more than four decades, downscaling of CMOS has been the fundamental strategy for improving the performance of VLSI circuits.

Fig-2: CMOS Half adder

In DSPs, and, versatile microprocessor, the wide-bit addition is vital in many applications such as ALUs, multiply-and accumulates (MAC) units. The half adder adds two single binary digits A and B. It has two outputs, sum (S) and carry (C). The carry signal represents an overflow into the next digit of a multi-digit addition. The value of the sum is A+B. The simplest half adder design incorporates an XOR gate for S and an AND gate for C. With the addition of an OR gate to combine their carry outputs, two half adders can be combined to make a full adder. The half adder adds two input bits and generates a carry and sum, which are the two outputs of a half adder.

2.3 XOR-XNOR CIRCUIT

Hybrid FAs are made of two modules, including 2-input XOR/XNOR (or simultaneous XOR–XNOR) gate and 2-to-1 multiplexer (2-1-MUX) gate. The XOR/XNOR gate is the major consumer of power in the FA cell. Therefore, the power consumption of the FA cell can be reduced by optimum designing of the XOR/XNOR gate. The XOR/XNOR gate has also many applications in digital circuits design. Many circuits have been proposed to implement XOR/XNOR gate which a few examples of the most efficient ones.

Fig-3: XOR-XNOR circuit

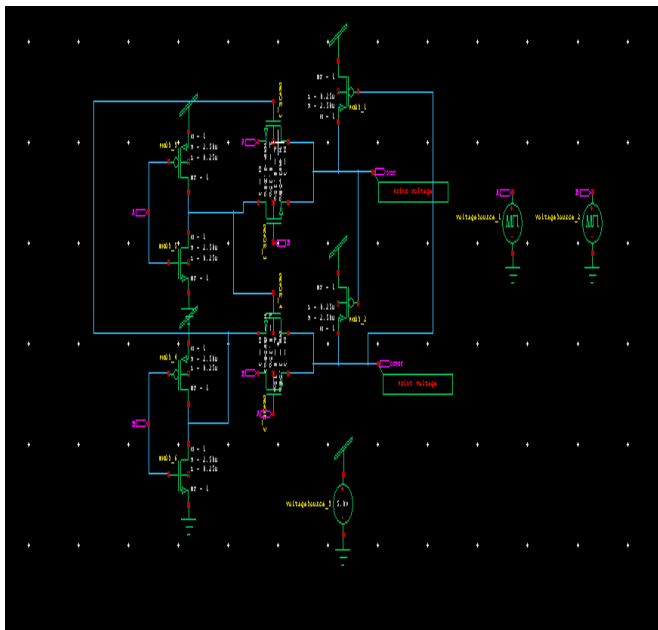

Fig-4 :XOR-XNOR circuit

The main problem of this circuit is using two high power consumption NOT gates on the critical path of the circuit, because the NOT gates must drive the output capacitance. Therefore, the size of the transistors in the NOT gates should be increased to obtain lower critical path delay. Furthermore, it causes the creation of an intermediate node with a large capacitance. Of course, this means that the NOT gates drives the output of circuit through, for example, pass transistor or TG. Therefore, the short circuit power and, thus, the total power dissipation of this circuit are widely increased. Moreover, in the optimum PDP situation, the critical path delay will also be increased slightly. Therefore, to improve the XNOR circuit speed, the size of PMOS transistor (P5)and NOT gates should be increased.

2.4 PROPOSED XOR-XNOR CIRCUIT

The proposed structure of the simultaneous XOR–XNOR gate consisting of 12 transistors. The proposed XOR/XNOR and simultaneous XOR–XNOR structures were compared with basic XOR-XNOR circuit. The results indicate that the performance of the proposed XOR/XNOR and simultaneous XOR–XNOR structures is better than that of the compared structures. The proposed XOR and XNOR circuits have the lowest PDP and delay, respectively, compared with other XOR/XNOR circuits. Also, the delay of these proposed circuits is very close together that prevents the creation of glitch on the next stage. The proposed circuit for simultaneous XOR–XNOR has better efficiency in all three calculated parameters (delay, power dissipation, and PDP) when it is compared with other XOR–XNOR gates

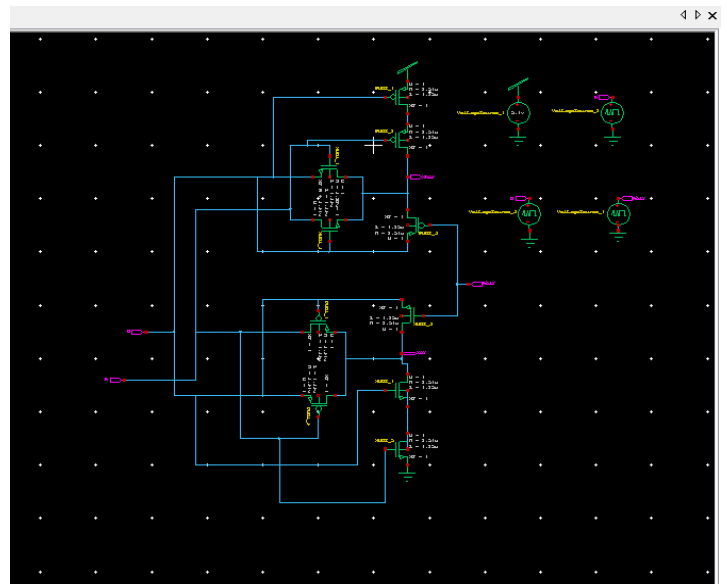

Fig-5:Proposed XOR-XNOR circuit

2.5 FULL ADDER CIRCUIT

Full adder is the adder which adds three inputs and produces two outputs. There are three types of basic structure on which full Adder is based static, dynamic and hybrid. Static full adders are less power consuming than dynamic and then more reliable. Dynamic full adder have faster switching speed, full swing voltage level and less number of transistors but suffer from charges haring, clock load, high power dissipation due to high switching activity and complexity. Hybrid full adder is basically the combination of static and dynamic full adder.

Fig-7 :Conventional CMOS Full adder

that of conventional CMOS full adder due to the reduction in the number of transistors. To produce the output Sum signal C and C compliment signals are used. The XOR, XNOR signals will be connected to the data select lines of 2-1-MUX. Due to the less capacitance of XOR and XNOR nodes the power consumption and delay of HFA 19T is less.

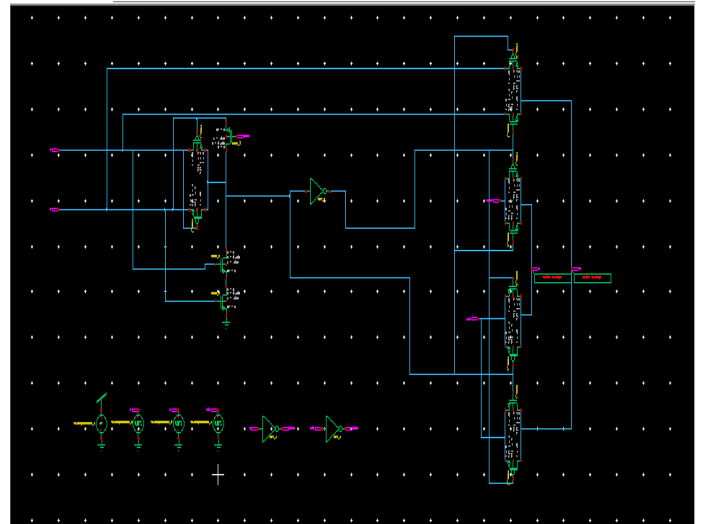

Fig-8 : Proposed Full Adder Circuit

3 RESULT AND ANALYSIS

The Tanner EDA tools were used to simulate the circuits. They offer complete design environment supporting analog/mixed-signal IC, MEMS and photonic design in highly integrated, end to end flow with an intuitive user interface for a quick learning curve and a low total cost of ownership through minimal IT support costs and competitive software license and maintenance costs.

3.1 WAVEFORM

Figure-9 depicts the obtained waveform of CMOS Inverter circuit

Fig-9: CMOS Inverter

2.6 PROPOSED FULL ADDER CIRCUIT

The new FA has been employed using switch hybrid logic style, and its designed by using the proposed XOR/XNOR circuit. The well-known four-transistor 2-1-MUX structure is used to implement the proposed hybrid FA cells. This 2-1-MUX is created with TG logic style that has no static and short-circuit power dissipation.

One way to reduce the power consumption of the FA structures is to use a XOR/XNOR gate and a NOT gates to generate the other XOR or XNOR signal. using the buffer on the output of a circuit is almost mandatory, especially in applications that the output capacitance of each stage is high. In practice, the driving capability of VLSI circuits is degraded due to the creation of the parasitic capacitors and resistors during the fabrication, as well as increasing the threshold voltage of transistors over the time, but the output buffer improves this situation.

The proposed HFA-19T is made by 19 transistors. The power consumption of proposed circuit is less than

Fig-14: Proposed Full adder Circuit

3.2 COMPARISON OF POWER AND DELAY

As far as electronic circuits are concerned, power consumption is a major bottleneck of system performance. The main source is the leakage power consumption, so the power is reduced by using XOR-XNOR topologies.

Table -1: Comparison of power and delay table

CIRCUIT	POWER (W)	DELAY
Inverter	7.124e-006	9.5701n
Half Adder	5.082e-004	10.3n
XOR-XNOR Circuit	5.957e-004	39.989n
Proposed XOR-XNOR Circuit	9.364e-005	10.409n
Conventional CMOS Full Adder	4.479e-004	39.986n
Proposed Full Adder - HFA 19T	2.009e-004	9.994n

4 CONCLUSION

This paper proposes various logic circuits with XOR-XNOR technique, which resulted in better terms of power consumption. Simulations are carried out and the power analysis has been performed. From the observation it is evident that the circuit with proposed XOR-XNOR is the efficient design with minimum power consumption. Hence the proposed architecture is well suited for modern high performance designs where power dissipation is the major concern.

ACKNOWLEDGEMENT

We would like to acknowledge the support of Department of Electronics and Communication and our HoD who provided us an opportunity and motivation to gain knowledge through this type of work. ABSTRACT

The application of organometallic compounds in biology and medicine is nothing new - indeed, nature has been using organometallic systems to sustain life for a rather long time. The misuse of antibiotics has led to the development of multi-drug-resistant bacteria, thus there is a need for development of new antimicrobials. Nanomaterials have tremendous potential in medical field. Conjugation of nanoparticles with organic compounds are performed to enhance the activity and to increase the stability of the NPs. In the present study, Zinc and Silver nanoparticles were synthesized and conjugated with the organic compound N-isopropylacrylamide (NIPAM). Bacterial inhibition of the NPs and NP–NIPAM conjugates were determined. Bacterial inhibition was determined against six different pathogens *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and *Enterobacter* sp. highest inhibitory zones were observed for *Enterococcus faecium* and *Staphylococcus aureus*. Inhibitory zones were found to be higher for Nps-PNIPAM composites than the Ag and Zn Nps. Zn-PNIPAM and Ag-PNIPAM composites showed 19mm and 18mm against *E. faecium*; and 17mm and 19mm against *S. aureus*. Fabrics coated with Zn-PNIPAM Ag-PNIPAM composites showed 31mm and 30mm against *E. faecium*; and 32mm and 28mm against *S. aureus*. The nanoparticles when combined with PNIPAM shows synergistic mode of action. Thus the Np-PNIPAM conjugates can be used as an potrntrnalternative to commercial antibiotics to treat drug resistant pathogens.

Keywords: Organometallics, nanoparticles, N-isopropylacrylamide, conjugates, bacterial inhibition assay

INTRODUCTION

The application of organometallic compounds in biology and medicine is nothing new - indeed, nature has been using organometallic systems to sustain life for a rather long time. The organometallic chemistry of cobalamine, better known as vitamin B12, and derivatives has been investigated for decades, along with that of a variety of enzymes and cofactors. However, many organometallic compounds are entirely stable to water and air, and while many do not show some toxicity to certain organisms, this property may be desirable for certain therapeutic applications (Coogan., 2012).

The misuse of antimicrobials has led to the development of multi-drug-resistant bacteria, which is one of the greatest challenges for healthcare practitioners and is a significant global threat. The major concern with the development of antimicrobial resistance is the spread of resistant organisms. The group of nosocomial pathogens that exhibits multidrug resistance and virulence are *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and *Enterobacter* sp and they are termed as *ESKAPE* pathogens. The replacement of conventional antimicrobials by new technology to counteract antimicrobial resistance is ongoing. Nanotechnology-driven innovations provide hope for patients and practitioners in overcoming the problem of drug resistance. Nanomaterials have tremendous potential in both the medical and veterinary fields. Several nanostructures comprising metallic particles have been developed to counteract microbial pathogens. The effectiveness of nanoparticles (NPs) depends on the interaction between the microorganism and the NPs. The development of effective nanomaterials requires in-depth knowledge of the physicochemical properties of NPs and the biological aspects of microorganisms (Gudepalya *et al.*, 2016). Among several nanoparticles Zinc and Silver has attracted a special attention as antibacterial agents. ZnO nanoparticles (ZnO-NPs) exhibit antibacterial activity and can reduce the attachment and viability of microbes on biomedical surfaces. Interestingly, several results suggest a selective toxicity of ZnO-NPs preferentially targeting prokaryotic systems, although killing of cancer cells has also been demonstrated (Hanley *et al.*, 2008).

AgO NPs and Ag-based compounds are highly toxic to several microorganisms, which make them interesting candidates for multiple applications in the medical field (Furno *et al.*, 2004; Prakash *et al.*, 2013). Ag is generally used as nitrate salt, but in the form of Ag nanoparticles (Ag-NPs) the surface area is increased and thereby antimicrobial efficacy is greatly enhanced. Though NPs find use in many biomedical applications, surface modifications of NPs like conjugation with organic compounds are performed to enhance the activity and to increase the stability of the NPs. Thus in the present study, Zinc and Silver nanoparticles were synthesized and conjugated with the organic compound N-isopropylacrylamide (NIPAM). Bacterial inhibition of the NPs and NP–NIPAM conjugates were determined against *ESKAPE* pathogens.

MATERIALS AND METHODS

Preparation of AgO nanoparticles (Maribel et al., 2009)

For the preparation of silver nanoparticles two stabilizing agents, Sodium Dodecyl Sulphate (SDS) and Citrate of sodium were used. For the synthesis of silver nanoparticles, silver nitrate solution (1mM) and 8% (w/w) Sodium Dodecyl Sulphate (SDS) were used as a metal salt precursor and a stabilizing agent, respectively. Hydrazine hydrate solution with a concentrate (2mM) and Citrate of sodium solution (1mM) were used as a reducing agent. Citrate of sodium was also used as stabilizing agent at room temperature. The transparent colourless solution was converted to the characteristic pale yellow and pale red colour, when citrate of sodium was used as stabilizing agent. The occurrence of colour was indicated the formation of silver nanoparticles. The silver nanoparticles were purified by centrifugation. To remove excess silver ions, the silver colloids were washed at least three times with deionized water.

Synthesis of Zinc oxide nanoparticles (Yadav et al., 2006)

The zinc oxide nanoparticles were prepared by wet chemical method using zinc nitrate and sodium hydroxide as precursors and soluble starch as stabilizing agent. Different concentrations of soluble starch (0.1%, 0.5% and 1.0%) were dissolved in 500 ml of distilled water by using microwave oven. Zinc nitrate, 14.874 g (0.1 M) was added in the above solution. Then the solution was kept under constant stirring using magnetic stirrer to completely dissolve the zinc nitrate. After complete dissolution of zinc nitrate, 0.2 M of sodium hydroxide solution (20 ml was used in our study) was added under constant stirring, drop by drop touching the walls of the vessel. The reaction was allowed to proceed for 2h after complete addition of sodium hydroxide. After the completion of reaction, the solution was allowed to settle for overnight and the supernatant solution was then discarded carefully. The remaining solution was centrifuged at 10,000 X g for 10min and the supernatant was discarded. Thus obtained nanoparticles were washed three times using distilled water. Washing was carried out to remove the by-products and the excessive starch that were bound with the nanoparticles. After washing, the nanoparticles were dried at 80°C for overnight. During drying, complete conversion of zinc hydroxide into zinc oxide takes place.

Preparation of Np-PNIPAM Composites (Ruben and Wolfgang., 2007)

Aqueous mixtures of 1mM silver nitrate and PNIPAM at indicated molar ratios of PNIPAM/Ag were prepared and stirred at room temperature. After 5 min of stirring, NaBH₄ was added to achieve a 3:1 molar ratio of NaBH₄/Ag⁺. The solution was stirred for 5 min to react and then immediately diluted with water to 4 times the volume to stop the reaction. The diluted solution was then heated to 40°C during centrifugation at 16 600g for 15 min to sequentially precipitate Ag-PNIPAM and then the polymer. The Ag-PNIPAM nanoparticles were recovered by centrifugation at 25 700g for 10 min and then resuspended in water. This process was performed twice, followed by freeze drying to recuperate the nanocomposite in a powder form for storage at -20°C. Similar procedure was carried out for preparation of Zn-PNIPAM composites. For preparation of Zn-PNIPAM composite Zinc nitrate is used.

Bacterial inhibition of the Nps and composite by well diffusion method

The synergistic antibacterial activity of the Nps and Np-PNIPAM Composites was determined against *ESKAPE* pathogens using a standard well diffusion method. MHA plates were prepared and swabbed evenly over its surface with 12h cultures of each test organisms. In the middle of the plate a 6mm well was cut using a sterile cork-borer. About 50µl of the samples were added under sterile conditions. All the plates were incubated at 37°C for 24h. The inhibitory zones around the well were measured in millimeter and recorded separately.

Finishing on fabrics and determining the bacterial inhibition assay of the finished fabrics

Np-PNIPAM Composites (1%) were resuspended in water. They were finished on fabrics by dip and dry coating procedure. The finished fabrics were dry at oven for 30mins at 50°C. The antibacterial activity of Np-PNIPAM Composites coated fabrics was tested using modified EN ISO-20743 test method against two test organisms. MHA plates were prepared by pouring 15 ml of media into sterile Petri dishes. The plates were allowed to solidify for 5 minutes and 0.1% inoculum was swabbed uniformly and allowed to dry for 5 minutes. The finished fabrics with the premeasured size of 20mm in diameter was placed on the surface of medium and the plates were kept for incubation at 37°C for 24 hours. Plain fabric without coating was also kept in the plate as control. At the end of incubation, the zone of inhibition formed around each material was measured in millimeter and recorded.

RESULTS AND DISCUSSION

Bacterial inhibition of the Nps and Np-PNIPAM composites

Bacterial inhibition analysis of the Zn Nps and Zn-PNIPAM composites was determined by well diffusion method. The inhibitory zones were measured in mm. *Enterococcus faecium* showed 14mm and 19mm for Zn Nps and Zn-PNIPAM. *Staphylococcus aureus* showed 12mm and 17mm for Zn Nps and Zn-PNIPAM. About 13mm, 11mm and 13mm of zones were obtained for Zn Nps and 18mm, 17mm and 18mm were observed for Zn-PNIPAM composites against *Klebsiella pneumonia*, *Acenitobacter baumannii* and *Proteus* sp. Antibacterial activity of the Ag Nps and Ag-PNIPAM composites was determined by well diffusion method. The inhibitory zones were measured in mm. *Enterococcus faecium* showed 11mm and 18mm for Zn Nps and Zn-PNIPAM. *Staphylococcus aureus* showed 12mm and 19mm for Ag Nps and Ag-PNIPAM. About 10mm, 11mm and 11mm of zones were obtained for Zn Nps and 17mm, 17mm and 16mm were observed for Zn-PNIPAM composites against *Klebsiella pneumonia*, *Acenitobacter baumannii* and *Proteus* sp.

Bacterial inhibition of the Np-PNIPAM composites finished fabrics

Finished fabrics were subjected to bacterial inhibition analysis against *ESKAPE* pathogens. *Enterococcus faecium* showed 26mm and 31mm for Zn Nps and Zn-PNIPAM finished fabrics. *Staphylococcus aureus* showed 24mm and 32mm for Zn Nps and Zn-PNIPAM finished fabrics. About 23mm, 23mm and 24mm of zones were

obtained for Zn Nps and 30mm, 29mm and 29mm were observed for Zn-NIPAM composites against *Klebsiella pneumonia*, *Acinetobacter baumannii* and *Proteus* sp. *Pseudomonas aeruginosa* showed 23mm and 27mm for Zn Nps and Zn-PNIPAM finished fabrics.

Ag Nps Coated and Ag-PNIPAM Finished fabrics were subjected to bacterial inhibition analysis against 6 pathogens. *Enterococcus faecium* showed 25mm and 30mm for Zn Nps and Zn-PNIPAM finished fabrics. *Staphylococcus aureus* showed 23mm and 28mm for Zn Nps and Zn-PNIPAM finished fabrics. About 22mm, 23mm and 24mm of zones were obtained for Zn Nps and 27mm, 28mm and 27mm were observed for Zn-NIPAM composites against *Klebsiella pneumonia*, *Acinetobacter baumannii* and *Proteus* sp. *Pseudomonas aeruginosa* showed 24mm and 26mm for Zn Nps and Zn-PNIPAM finished fabrics.

DISCUSSION

Recently, nanotechnology has become increasingly important in the biomedical and pharmaceutical area as an alternative antimicrobial strategy due to re-emergence infectious diseases and the appearance of antibiotic-resistant strains especially within Gram-negative microorganisms (Desselberger, 2000). The present research focuses on development of silver and Zinc nanoparticles. The Nps-NIPAM conjugates were also prepared and subjected to bacterial inhibition analysis. Silver and Zinc nanoparticles have unique properties which help in molecular diagnostics, in therapies, as well as in devices that are used in several medical procedures.

The mechanism of action of the antibacterial activity of AgNPs is attacking the respiratory chain and cell division that ultimately leads to cell death. The silver nanoparticles have also been reported to release silver ions inside the bacterial cells, further enhancing their bactericidal activity (Qing *et al.*, 2018). It has also been proposed that there can be release of silver ions by the nanoparticles, and these ions can interact with the thiol groups of many vital enzymes and inactivate them. The bacterial cells in contact with silver take in silver ions, which inhibit several functions in the cell and damage the cells. Then, there is the generation of reactive oxygen species, which are produced possibly through the inhibition of a respiratory enzyme by silver ions and attack the cell itself. Silver is a soft acid, and there is a natural tendency of an acid to react with a base, in this case, a soft acid to react with a soft base (Prabhu and Eldho., 2012). The cells are majorly made up of sulfur and phosphorus which are soft bases. The action of these nanoparticles on the cell can cause the reaction to take place and subsequently lead to cell death. Another fact is that the DNA has sulfur and phosphorus as its major components; the nanoparticles can act on these soft bases and destroy the DNA which would definitely lead to cell death. The interaction of the silver nanoparticles with the sulfur and phosphorus of the DNA can lead to problems in the DNA replication of the bacteria and thus terminate the microbes.

Silver nanoparticles find use in various other fields, and the major applications include their use as catalysts, as optical sensors of zeptomole (10^{-21}) concentration, in textile engineering, in electronics, in optics, and most importantly in the medical field as a bactericidal and as a therapeutic agent. Silver ions are used in the formulation of

dental resin composites; in coatings of medical devices; as a bactericidal coating in water filters; as an antimicrobial agent in air sanitizer sprays, pillows, respirators, socks, wet wipes, detergents, soaps, shampoos, toothpastes, washing machines, and many other consumer products; as bone cement; and in many wound dressings to name a few (Tashi *et al.*, 2016).

Zinc oxide nanoparticles are generally less toxic than silver nanoparticles in a broad range of concentrations (20 to 100 mg/l) with average particle size of 480 nm. It is universally known that zinc oxide nanoparticles are antibacterial and inhibit the growth of microorganisms by permeating into the cell membrane. The oxidative stress damages lipids, carbohydrates, proteins, and DNA. Lipid peroxidation is obviously the most crucial that leads to alteration in cell membrane which eventually disrupt vital cellular functions. It has been supported by oxidative stress mechanism involving zinc oxide nanoparticle in *Enterococcus faecium*. Two mechanisms of action have been proposed for the toxicity of zinc oxide nanoparticles, namely (1) generation of ROS and (2) induction of apoptosis. Metal oxide nanoparticles induce ROS production and put the cells under oxidative stress causing damage to cellular components, i.e., lipids, proteins, and DNA. Zinc oxide nanoparticles, therefore, induce toxicity through apoptosis. They are relatively more toxic to cancer cells than normal cells, although they cannot distinguish between them (Khwaja *et al.*, 2018).

Significant inhibitory zones were observed for Zinc and Silver nanoparticles. Thus, our results well correlate with the previous studies of the other authors. In order to increase the stability of the nanoparticles N-isopropylacrylamide (PNIPAM) were conjugated with the zinc and silver nanoparticles. The inhibitory zones were found to be higher for the conjugates i.e the PNIPAM also exerts bacterial inhibition. The nanoparticles when combined with PNIPAM shows synergistic mode of action. Conjugation of metals with PNIPAM has many advantages including excellent bio-compatibility, good stability, extensive adsorption of proteins, large surface-to-volume ratio, and controllable particle size (Sun *et al.*, 2019).

CONCLUSION

Zinc and Silver nanoparticles were synthesized and conjugated with the organic compound N-isopropylacrylamide (NIPAM). Bacterial inhibition of the NPs and NP–NIPAM conjugates were determined. Bacterial inhibition was determined against six different pathogens *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumonia*, *Acinetobacter baumannii* and *Proteus* sp. Highest inhibitory zones were observed for *Enterococcus faecium* and *Staphylococcus aureus*. Inhibitory zones were found to be higher for Nps-PNIPAM composites than the Ag and Zn Nps. Zn-PNIPAM and Ag-PNIPAM composites showed 19mm and 18mm against *E. faecium*; and 17mm and 19mm against *S. aureus*. Zn Nps and Zn-PNIPAM composites showed 14mm and 19mm against *E. faecium*; 12mm and 17mm against *S. aureus*. Ag Nps and Ag-PNIPAM composites showed 11mm and 18mm against *E. faecium*; 12mm and 19mm against *S. aureus*. Fabrics coated with Zn-PNIPAM Ag-PNIPAM composites showed 31mm and 30mm against *E. faecium*; and 32mm and 28mm against *S. aureus*. The nanoparticles when combined with PNIPAM shows synergistic mode of action. Thus the Np-PNIPAM conjugates can be used as an alternative to commercial antibiotics to treat drug resistant pathogens.

Drip Curing Technique on Concrete For Water Conservation And Improved Compressive Strength

Alwyn Varghese, K.P. Megha, Reshma.S, Sneha chandran.V

Abstract— Concrete and its curing is an inevitable process of any construction. Curing of concrete is the process of maintaining satisfactory moisture content in concrete during its early stages in order to develop the desired properties for concrete such as developing the concrete microstructure and pore structure thereby improving its durability and performance. Water is largely used in curing process and is becoming a scarce material day by day. Even if the conventional concrete mix used has various advantages it also has disadvantages as cracking, low strength, high water consumption and brittleness. There is an urgent need to do research work pertaining to saving of water and improving strength of concrete by making modifications in curing process. The study leads to comparison of 3ways of curing techniques by means of compressive strength at 28th day. In this study the IS standard specimen tested and identified drip curing method is adaptable for different concrete need of construction. Also for curing, the drip curing method inspired from the drip irrigation system is used. This combination results in conservation of water without compromising properties of concrete.

Index Terms— Ceramic waste aggregate, Compressive strength, Concrete, Drip irrigation, Drip curing, Curing, Strength, Water conservation

1 INTRODUCTION

Concrete reduce the growth of strength gain at its early stages due to improper curing that leads the concrete not achieving the desired compressive strength. It makes the failure of total structure. The vertical member like column, in particular, is one of the most victimized RCC element-which must be carefully cured, as the entire dead and live load of super structures are supported by columns and transferred to the foundation. Unfortunately, adequate curing is not given much importance at most of the sites and traditional methods of curing are adopted, which leads to reduction in durability of the structure [1]. The improper curing causes loss in large amount of water, evaporation of water from surface and reduction in the durability of the concrete [2]. In major cities it is banned to use domestic supply of water supplied by corporation to use [tap water] for the purpose of construction.

It is evident in form of cracks which are easily noticeable by naked eye. Unfortunately adequate curing is not given much important at most of the sites and traditional methods of curing are adopted which leads to reduction in durability of concrete and loss of large quantity water [3]. Here a comparison on 3 types of curing is done-they are immersion curing, spraying and drip curing. These types are done on normal concrete mix (M20) and also concrete containing Ceramic Waste Fine Aggregate (CWFA).

containing CWFA as per IS standards (15cm x 15cm x 15cm) are casted and tested. Studies have been done in importance of curing but no study had occurred in analyzing advantages of drip curing on concrete containing CWFA.

2 MATERIALS AND METHODOLOGY

The properties of constant materials and details of mix proportion are shown in table 1. Table 2 shows that M20 (CC) grade concrete mix proportion.

TABLE 1
PROPERTIES OF CONSTANT MATERIALS

MATERIALS	DENSITY (Kg/m ³)	SPECIFIC GRAVITY	SURFACE MOISTURE
Cement	1438	3.15	-
Fine aggregate	1620	2.74	Nil
Coarse aggregate	1800	2.90	Nil
CWFA	1700	2.78	Nil

Table 1 shows that CWFA have almost same density and specific gravity as fine aggregate and coarse aggregate. Ceramic waste are higher resistant to chemical, biological and physical degradation forces and are durable and harder. The properties of these materials make them a good and suitable choice that can be used in concrete. The use of ceramic waste in concrete effects the characteristics of green and hardened concrete and make it more durable.

For the study purpose a normal concrete cube and concrete

TABLE 2
CONCRETE MIX PROPORTION

CEMENT(Kg)	FINE AGGRE-GATE(Kg)	COARSE AGGRE-GATE(Kg)	W/C RA-TIO
339	754	1290	0.53

Table 2 shows that mix proportion of M20 concrete with water cement ratio of 0.53.

2.1 Preparation of CWFA

Ceramic wastes sourced from construction and demolition wastes where crushed using a quarry metal hammer. It was sieved into fine aggregate according to the standards. This aggregate was used in the preparation of rapid curing compound by replacing conventional aggregates in various Percentages (5%, 10%, 15%, 20%, 25% and 30%) and concrete was produced. Cube was casted and cured as above mentioned three types of curing methods. 28 days compressive strength of these cubes were found according to type of curing method [5].

3 TEST PROCEDURES

The 15 x 15 x 15 cm specified concrete cube casted and cured as per different curing methods as immersion, spraying and drip up to the age of 28 days. After removal of moisture content in the specimen it is tested for compressive strength of concrete as Figure 1.

Fig. 1 Testing of cube in universal testing machine

3.1 IMMERSION CURING

In this concrete cubes are submerged into the water tank till the curing period gets over and every time the buckets are topped up with water to compensate the loss of water due to exothermic reaction of concrete. In this concrete gets in contact with the water for almost all the time and thus the water requirement for concrete is 100% [4].

3.2 SPRYING

Sprinkling of water continuously on the concrete surface pro-

vides an efficient curing. Spraying of water is only started after the final setting period of 10 hrs. The concrete cube is kept wet continuously by sprinkling water on the surface [3].

3.3 DRIP CURING

At site a number of pipes are used for drip curing. The network consists of mains, sub mains, secondary pipe, tertiary pipes and drip pipes. The drip pipes are the largest member of network which is kept in contact with concrete (figure 2). These pipes are connected to mains. The water is supplied to mains from an overhead water tank by gravity. The discharge is controlled by a nob attached to the main [5].

Fig. 2 The concrete cube enclosed with drip pipes.

4 METHODOLOGY

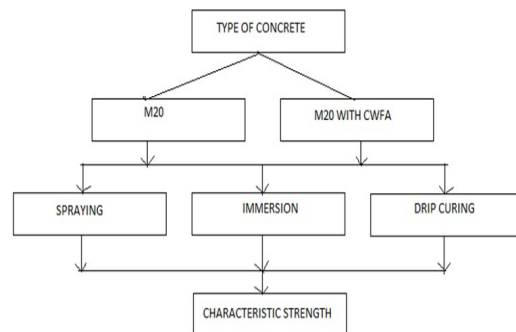

Fig. 3 methodology of reserch

Figure 3 shows that the testing procedure of research. In this three types curing method s are adopted for strength at-taining for concrete at early ages (28 days)[6]. After each method of curing the specimens are tested and analysed in the terms of variation of compressive strength.

5 RESULTS AND DISCUSSION

TABLE 3
COMPRESSIVE STRENGTH OF CONCRETE

NAME OF MIX	CURING METHOD		
	SPRAYING	IMMERSION	DRIP
CC	19.51	20.1	21.33

TABLE 4
COMPRESSIVE STRENGTH OF VARIOUS MIXES UNDER DIFFERENT CURING METHODS

NAME OF MIX	% OF CWFA	CURING METHOD		
		SPRAY-ING	IMMER-SION	DRIP
CWFA-5	5	19.4	19.6	20.1
CWFA-10	10	19.6	19.9	20.2
CWFA-15	15	19.2	20.6	20.8
CWFA-20	20	19.7	21.2	21.6
CWFA-25	25	21.7	23.1	24.2
CWFA-30	30	19.8	20.1	20.8

Table 3 shows that the higher value of compressive strength of cc cube was obtained with drip curing compared to other two method of curing. Drip curing method was able to give a compressive strength of 21.33N/mm² which is the maximum out of other two methods. It may be due to countiuous moisture content at required level makes to prevent the water evaporation from the concrete when the C-S-H gel formation taken place.

Table 4 shows that the new concrete mix containing replacement of fine aggregate with CWFA was able to give higher compressive strength than that of CC cube. From the test conducted it was found that maximum percentage of CWFA as replacement of fine aggregate was 25%. Beyond this percentage of addition the compressive strength went on decreasing. It may be due to the small quantity of fine aggregate does not effect the strength of concrete. But the large quantity makes the change of zone in fine aggregate. It makes to degradation of compressive strength. Also the best result was obtained when the cube was provided with drip curing technique.

Practically drip curing is the most effective method of curing. It produced the highest level of compressive strength practically at site. This is due to non stop supply of required water

to cool down the exothermic reaction of concrete, resulting from greater degree of cement hydration reaction uniformly. Since the water spreads over the area giving the concrete to absorb water and fulfill its water requirement. Without compromising with the quality and strength of concrete we can achieve the result with very less quantity of water.

Effect of Diameter of Reinforced Bar in Various Fiber Reinforced Concretes

Alwyn Varghese, Harikrishnan T P, Haritha K, Mohammed Razeem S M

Abstract: An experimental investigation has been carried out to determine the effect of fibers on the bond strength of different grades (M20 and M50) of concrete by using reinforced bars of different diameters (10mm and 12mm). Different types of fibers such as glass, polypropylene, basalt were used in the preparation of concrete mix with 0.25% of volume proportion. Then the bond strength was determined by the pull-out test as per IS 2770 (part 1). Based on the test results of the study, grade of concrete, type of fibers and different diameter of reinforcement bar are the key parameters that affect the bond strength of concrete. The contribution of basalt fiber in enhancing the bond strength was found to be more significant compared to other fibers (8.227 N/mm² for M20 concrete and 9.323 N/mm² for M50 concrete). The bond strength has been improved slightly by increasing the diameter of the reinforcement bar. Durability analysis was carried out by curing specimens in HCl and H₂SO₄. Fibers don't have sufficient influence in the durability of concrete.

Index Terms: Bond Strength, Durability, FRC, Pull out test.

I. INTRODUCTION

Concrete is one of the cheapest material with desired strength in the construction industry. Advancements were done in the concrete to develop its manufacture and utilization. Being a weak tensile material, several cracks formed during loading and so on. These cracks are formed because of the internal micro cracks, resistance of material to resist the tensile forces and environmental factors. Some researchers found some fiber which are effective with concrete to reduce the crack propagation. Fibers which are added in concrete will act as a tensile member and transfer load on these micro-cracks propagated area [1-4]. Fiber Reinforced Concrete (FRC) can also improve the bond strength between concrete and reinforcement [5-6].

Inclusion of Basalt Fiber (BF) will improve the toughness, reduce brittleness, tensile strength, resistance to deform and rupture modulus of concrete [7]. BF has better tensile strength than the E-glass fiber as well as greater failure strain than carbon fiber. BF also resist chemical attack, impact load and fire [7-8].

Shrinkage cracking can be controlled by adding Glass Fiber (GF). It will also improve flexural strength of concrete. GF also possess post-peak ductility in compression [9]. Glass Fiber Reinforced Concrete (GFRC) prepared with high

strength, alkali-resistance glass fiber embedded in concrete matrix [10]. GF can be used as either in continuous or chopped lengths. GF are comparatively available in local market with low prize. Studies have shown that the addition of glass fibers in concrete can control shrinkage cracking, improve flexural and tensile strength [6] [11-12]

Addition of Polypropylene Fiber (PPF) in concrete will improve its ductility toughness, and impact resistance [13]. PPF utilized in concrete mix at relatively low volume fractions which helps to control plastic shrinkage cracking of concrete [13-14].

Environment has a greater impact on durability of a concrete structures. The constituents present in environment that includes chemicals, gases, dust particles and so on are the major causes of corrosion in the reinforcement that leads to deterioration in concrete structures [2].

Pull out tests is an important test for evaluating bond strength between concrete and embedded reinforcement and for durability chemical attack test by immersing the concrete cubes in an acid solution is conducted [1-2].

In reinforced concrete structure, bond strength is one of the most important and significant factor as it is dealt with the overall strength and serviceability of a structure. Bond strength is defined as the effective grip or adhesive forces between the reinforced bars and embedded concrete whereas durability is associated with the environmental impacts. The effect of fibers in plain concrete for the bond strength and durability is analyzed in this paper. The objective of this investigation is to analyze bond strength characteristics and durability aspects of FRC with BF, GF, and PPF in various cases such as changes in grade of concrete and changes in diameter of the reinforcing bar.

Revised Manuscript Received on June 15, 2019.

Alwyn Varghese, Asst. Prof., Civil Department, Ahalia School of Engineering and Technology, Palakkad, Kerala, India.,

Harikrishnan T. P, Haritha K. & Mohammed Razeem S M, B-tech student, Civil Department, Ahalia School of Engineering and Technology, Palakkad, Kerala, India.

Ordinary Portland Cement (OPC) of 53 grade, Artificial sand (M Sand) of zone III having specific gravity of 2.6 is used as fine aggregate and 12mm sized crushed stones were used as coarse aggregates. Chopped fibers of basalt, glass and polypropylene were used in a specified mix proportions to cast the specimens. Table 1 shows the properties of fibers, which used in this study and fig. 1 is the images of used fibers.

Fig. 1 Types of fibers used

B. Specimen Preparation

Materials were tested for calculating mix design and prepared mix proportions for two different grades (M20 and M50). Three trial specimen samples were casted for each testing. Table 2 shows the mix proportions of concrete used in this study. The concrete specimens were prepared by mixing cement, artificial sand, coarse aggregates and fibres as per the codal provision IS 2770: 1967 part (1). Superplasticizer of Fosroc Auramix V200 was used to adjust the workability of the concrete mix. The optimum dosage were determined by trials using the materials and conditions that will be experienced in use. The normal dosage range is in between 0.1 to 0.5 by cementitious materials.

Table 2: Mix Proportion for specimens

Mix	Water Cement ratio	Cement	Fine aggregate	Coarse aggregate
M20	0.5	1	1.95	2.95
M50	0.34	1	1.66	2.5

Fig. 2 Specimens for pull out test

A total of 96 specimens were casted for both pull out tests and durability tests that includes cubes with and without fibers. 48 Concrete cubes sized 100×100×100mm cubes without reinforcement were casted and cured in water for 28 days. Three trials of specimen were casted for each fiber mixes for each grade of concrete. The concrete cube specimens of 100×100×100 mm along with steel

reinforcement were cast and kept in a curing tank for 28 days. Reinforcement of diameter 10 mm and 12 mm was inserted into fresh concrete specimen for a length of 100 mm. And also 10 mm projection of reinforcement at the bottom of cube was provided as per coded provision (IS 2770: 1967 part (1)).

After curing the specimens were subjected to pullout test and durability tests. Fig 2 shows the samples of prepared specimens for pull out tests.

C. Test Setup

Pull-out test

As per IS 2770: 1967 part (1), pullout test was carried out using Universal Testing Machine (UTM). A total of forty eight specimens were prepared with three types of fibers (GF, BF and PPF) and without fiber, for different grades of concrete (M20 and M50), and for different diameters of bars (10mm and 12mm). The specimen was placed in the UTM in such a way that the bar could be pulled axially from the cube. In this study, load and slip of reinforcing bar were noted in a number of intervals throughout the test up to a slip of 2.5 mm. For each intervals slip values are noted by using deflection meter with a least count of 0.002 mm. Fig 3 and fig 4 are the images of deflection meter connected to the UTM setup. Bond stress for each specimen was calculated by dividing the applied load at the end specified and the surface area of the embedded length of the bar.

Fig. 3 UTM

Fig. 4 Deflection meter

Durability test

Chemical resistance of concrete was studied through chemical attack by immersing them in H₂SO₄ and HCl acid solutions. 100 mm x 100mm x100mm sized cube specimens were casted as per IS 2770-PART 1: 1967. Twenty four cubes of M20 and M50 grades of concrete (with and without fibers) were immersed in water for 28 days. Then the specimen weighed and inserted into 5% acid solution. The P-H of the solution is maintained continuously for the entire curing period. Each cube is taken out after 28 days of acid curing and weighed again. Durability was analyzed by the weight loss of cubes.

III. METHODOLOGY

Bond strength of different grades of reference concrete (Rc), i.e.; specimen without fibers and FRC were determined by using pull-out test. Fig. 5 shows the methodology of the entire work.

Fig. 5 Methodology

The bond stress values of different grades of concrete (M20 and M50) were compared to find the difference in bond stress. Also specimens with different diameter of bars were compared for analysis. Fig. 6 shows the actual view of experimental setup on UTM. The slip at the loaded end of bar was calculated by the average of reading given by the dial gauges for three trials of specimens. The average bond stress value for each specimen was calculated by dividing the applied load by the surface area of the embedded length of bar. The increase in bond strength when adding different fibers was calculated. And the effect in bond strength when changing the diameter of steel bar was found out.

Fig. 6 Pullout test set up

The weight of specimen after 28 days of water curing before acid test was noted. The weight of specimen was again noted after 28 days of acid curing. Then the loss of weight of specimen after acid curing was calculated by determine the difference between two weights and then found out the

percentage of weight loss.

IV. RESULTS AND DISCUSSIONS

A. Pull- out Test

All specimens failed by vertical crack formation when subjected to pull-out test as shown in fig. 7. It can be seen that fibers assist in reducing the cracks in concrete elements. Addition of fibers in concrete can make an improvement in tensile properties of concrete in all directions.

Fig. 7 Crack pattern

Fig. 8 shows the deflection of M20 specimens under 10 mm bar up to 2.5mm slip. M20 grade of Basalt Fiber Reinforced Concrete (BFRC) has higher bond strength of 7.183 N/mm². M20 grade of concrete without fiber (Rc) specimen was the least among the FRC with a value of 5.116 N/mm².

Fig. 8 Bond Strength of M20 R_c and M20 FRC (10mm bar) up to 2.5mm

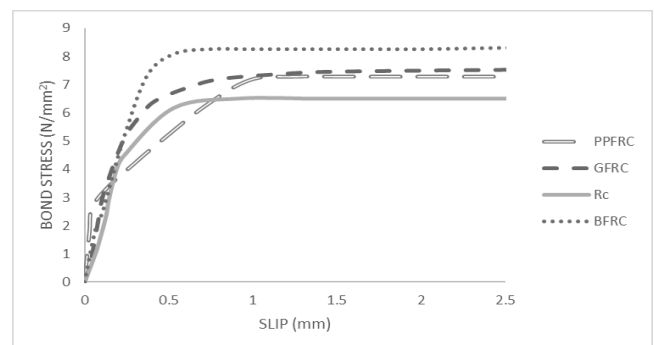

Fig. 9 Bond Strength of M20 R_c and M20 FRC (12mm bar) up to 2.5mm

Fig. 9 shows the deflection of M20 specimens with 12mm reinforced bar. Also BFRC shows the highest bond strength of 8.227 N/mm² followed by Glass Fiber Reinforced Concrete (GFRC), Polypropylene Fiber Reinforced Concrete (PPFRC) and Rc

Fig. 10 Bond Strength of M50 Rc and M50 FRC (10mm bar) up to 2.5mm

Fig. 10 shows the bond strength of M50 grade of concrete specimens with 10mm reinforcement bar up to 2.5mm slip. M50 specimens have a higher bond strength than M20 specimens for each mixes. Also bond stress of BFRC has a high value of 8.639 N/mm². Other mixes also followed the similar mode of increase.

Fig. 11 Bond Strength of M50 Rc and M50 FRC (12mm bar) up to 2.5mm

Fig. 11 shows the deflection of M50 specimens with 12mm bar up to 2.5 mm slip. Concrete with BF had the highest strength and that was followed by GF and PPF. The bond strength of the concrete without fiber was the least among the FRC's. The bond strength of specimen was increased when adding fiber having high young's modulus [15].

From the experiments, it is observed that bond strength of BFRC is higher than that of concrete with GF, PPF and Rc for all grades of concrete. BF does not possess chemical reaction with other materials. It may be the reason for the high bond strength of BFRC [16-17]. GFRC possess more bond strength than PPFRC and Rc. Higher elastic modulus of GF than PPF may be responsible for its high bond strength [15].

It is found that PPFRC specimens have more bond strength

than Rc specimens. Flexural ductility and long-term durability of concrete can improve by adding PPF [18]. It can reduce the plastic shrinkage of concrete [19]. Propagation of micro cracks of concrete can be reduced by adding PPF. It will fills the holes within the mortar and thus reduces porosity [20].

The difference of bond strength of M20 concrete specimens with 10 mm bar and 12 mm bar is shown in fig. 12. Final value of bond stress is the final crack load of the specimen in the apparatus. From the fig. it is clear that the bond strength of M20 grade of concrete specimen with 12 mm reinforced bar is higher than that with 10 mm reinforced bar. The BFRC specimen shows a higher bond stress than that of other FRCs.

Fig.12 Bond Strength Comparison of M20 grade concrete with 10mm and 12mm bar

Fig.13 Bond Strength Comparison of M50 grade concrete with 10mm and 12mm bar

Bond strength of different M50 grade of concrete specimens with 10 mm and 12 mm diameter reinforced bars is shown in fig. 13. M50 grade of concrete specimens had comparatively higher bond strength than M20 grade of concrete specimens. BFRC had higher bond strength than that of other FRC's. Bond strength is improved slightly for specimens with 12 mm diameter reinforced bar.

The diameter of steel reinforcement used in a Pullout test specimen has an important role in the improvement of bond stress. From Table 3, it is clear that bond strength increases with increasing the diameter of reinforced bars. According to IS 2770:1967 (part 1)

$$\text{Bond stress} = P/\pi D l$$

Where P is the load acting on the specimen,
D is the diameter of the reinforcement,
l is the length of reinforcement bar inside the specimen.

Table 3: Percentage increase in bond strength based on diameter of bar

Mix	Type of concrete	Bond strength		% Increase in bond strength
		(N/mm ²) 10mm	12mm	
M20	BFRC	7.183	8.227	10.43
	GFRC	6.672	7.556	8.83
	PPFRC	6.339	7.241	9.01
	R _c	5.116	6.502	13.86
M50	BFRC	8.639	9.323	6.83
	GFRC	8.568	8.934	3.65
	PPFRC	7.710	8.206	4.95
	R _c	5.288	6.597	13.08

The specimen with 12mm reinforced bar can withstand more pullout load than specimen with 10mm reinforced bar. Table 3 shows the percentage of increase in bond strength

Table 4: Durability test results

Grade of concrete	Mix	Initial weight		Weight after 28 days (kg)		% Weight loss after 28 days (%)	
		HCl	H ₂ SO ₄	HCl	H ₂ SO ₄	HCl	H ₂ SO ₄
M20	R _c	2.43	2.24	2.4	2.21	1.23	1.34
	GFRC	2.33	2.45	2.295	2.395	1.50	2.24
	BFRC	2.285	2.58	2.245	2.53	1.75	1.94
	PPFRC	2.415	2.425	2.375	2.38	1.66	1.86
M50	R _c	2.385	2.45	2.345	2.405	1.68	1.84
	GFRC	2.47	2.58	2.425	2.525	1.82	2.13
	BFRC	2.55	2.855	2.495	2.78	2.16	2.63
	PPFRC	2.4	2.15	2.36	2.11	1.67	1.86

V. CONCLUSIONS

From the experimental study, the following conclusions can be drawn.

- BFRC shows higher bond strength than other FRCs, in both grades of concrete.
- M50 FRCs have higher bond strength than M20 FRCs.
- Specimens made up of 12mm reinforcing bars have higher bond strength than that of specimens

with increase in the diameter of bars. For M20 grade of concrete BFRC shows 10.43% increase in bond strength when using 12 mm bar whereas the bond strength of R_c specimen is increased by 13.86%. GFRC has comparatively less value of 8.83%. For M50 grade of concrete, bond strength of R_c specimen is increased by 13.08%. GFRC has the least value of 3.65%. The increase in the diameter of reinforced bar is more affects the M50 grade of concrete specimens than M20 grade of concrete specimens.

B. Durability Test

The loss of weight for different grades of FRC is given in Table 4. Cubes subjected to H₂SO₄ curing shows higher weight loss than cubes subjected to HCl solution. It is also analyzed that FRC specimens had comparatively high weight loss after 28 days of acid curing than R_c specimen. For M20 grade of concrete specimens, BFRC has 1.75% weight loss in HCl and 1.94% weight loss in H₂SO₄, which is higher among other FRCs. R_c specimen has 1.23% and 1.34% weight loss for HCl and H₂SO₄ respectively. For M50 grade of concrete specimens, R_c specimens have a less weight loss of 1.68% for HCl and 1.84% for H₂SO₄. Weight loss increase in an order of PPFRC, GFRC and BFRC. Percentage of weight loss was increased with addition of fibers [16]. Fiber addition reduced the weight of all specimens, when subjected to durability test. More over weight loss of FRC specimens were increased by increase in fiber dosage [21].

with 10mm reinforcing bars.

- M20 grade of BFRC specimen shows 10.43% increase in bond strength when increasing the diameter of reinforcing bar from 10mm to 12mm. It is comparatively higher than that of other M20 grades of FRCs.

- M50 grade of BFRC specimens shows 6.83% increase in bond strength when increasing the diameter of reinforcing bar from 10mm to 12mm.
- The addition of fiber in concrete has no significant influence in its durability.
- Durability reduces with the addition of fiber in concrete in both grades subjected to acid curing for 28 days.
- Specimens cured in H₂SO₄ solution have higher weight loss than specimens cured in HCl.
- The addition of BF in concrete shows higher weight loss than other fibers and PPF is the least.
- Weight loss of specimens cannot be reduced by improving the grade of concrete.

Ergonomic Building Design Consideration of an Earlylearning Centre

Prof. Alwyn Varghese, Aishwarya.N, Darsana.S, Deepthi C.P ,Nayana.N , Saranya.R

Dept. of Civil Engineering, Ahalia School of Engineering and Technology, Kerala, India

Abstract - Children training through game playing are more effective than traditional academic methods. Therefore effective training can be one of the ways for improving the children's capabilities and development. The purpose of the project is to plan and design an 'Early learning centre' according to the standard parameters, which will end to more secure and safe doors, windows, playground, emergency consideration etc. are studied. This project is intended to provide a model in designing environment for kids. Various parameters such as floor area for indoor as well as outdoor activities, their shapes and position, natural and artificial lighting, door-ways and a child care following Indian standard which is functional in their design, cost effective to operate and environmentally safe and secure. Anthropometric measurements of children are also considered while planning the childcare as they are essential to ensure the safety and security and are crucial to the child's development and experience.

Key Words: Early learning centre, Anthropometry, Parameters

1. INTRODUCTION

Early education plays in improving a child's future academic performance, health and quality of life. The quality of this environment has a profound influence, especially given that many children spend close to half working hours in a childcare center. The 'Early learning center' is a place where children experience the world and through which care givers and the community gave support.

Learning is an active process whereby the opportunity to explore and interact with the development. key components in a child's growth and sequence A child's growth follows a developmental environment are that is universal, but that within that sequence, each child proceeds at different rate and in unique ways.

Early childhood education or early learning centre is a branch of education theory which relates to the teaching of young children (formally and informally) up until the age of about eight. Infant/toddler education, a subset of early childhood education, denotes the education of children from age two to age four and half years.

Hence there is a need to provide stimulating and developmentally appropriate challenges for the individual child in a warm, secure, environment. The aim of the center is to provide consistent, high quality care to meet the needs of the active, continually developing child.

2. METHODOLOGY

When designing a space or product we must know the body dimensions of the prospective user. Reason for applying ergonomic design are that accidents, reduced productivity, ineffectiveness and user discomfort may arise from incorrect product dimension that do not match those of the user.

Anthropometric is a term used to describe the measurements of a user population for which the space is designed. Measurements are reported in terms of the range of body measurements of the particular population.

It is a well-known fact that there are serious ergonomic problem among the preschool children and toddlers of India. In fact proper design guideline for an early learning center does not exist in our country. The absence of reliable ergonomic and anthropometric data of school aged children, which measurements take in to account the application for which the children living and working spaces, furniture and equipment are designed as well as the dimensions of the children, can serve as the national in attentiveness to design principles of an ELC.

In light of these problems and in the absence of data, the following methodology was under taken to meet the urgent need for the design guideline of an ELC.

Firstly, it is need to be known who you are designing for. The group you are designing for is called user population. We consider 2.5, 3, 3.5,4 and 4.5 year old children as the user population. The anthropometric data of children of these age group were collected from Ahalia public school. The measurements of 14 anthropometric characteristics of children which constitute a set of basic data for the design of functional spaces and furniture were used. The children were made to be in sitting and standing positions to take both static as well as dynamic measurements. Next the optimum values of the furniture were calculated based on the anthropometric data previously acquired. In calculating the optimum dimensions, dynamic or static anthropometric measures, minimum and maximum values, and also the function of the furniture were taken in to considerations. All of the furniture was divided in to two groups according to reach and volumetric function based on the main criteria of anthropometric design. The different formulas for calculating the optimum values of different furniture is obtained as follows,

Maximum values were calculated for volume measurements.

$$\text{Furniture dimension} = X + (\text{SD} \times Z)$$

Minimum values were calculated for reach measurements,

Furniture dimension= $X - (SD \times Z)$

where, X is the mean and SD is the standard deviation of the anthropometric measurements of different age group children. Z is a constant value corresponding to 95 percentile confidence interval.

The next step of our project was to provide suggestions for the various parameters we identified through literature review. The parameters are

- Green building
- Space arrangements
- Openings
 - ✓ Doors
 - ✓ Windows
- Hard ware locations in doors
- Materials
 - ✓ doors and window materials
 - ✓ flooring materials
 - ✓ roofing materials
- finishes
 - ✓ ceiling finishes
 - ✓ wall finishes
 - ✓ floor finishes
 - ✓ skirting of tiles
- color
- fire protection, environmental and safety issues
- Child safety.

2.1 DESIGN OF FURNITURES FOR ELC

The dimensions of the living and working space of buildings, the types of material and different riggings should be designed to conform to the user's anthropometric measures. Anthropometric measures are the most frequently used ergonomic data during the design process. In our project, anthropometric data is used in the design of children's equipment and furniture used in an Early Learning center. The anthropometric data of 2.5, 3, 3.5, 4, and 4.5 years old children were used for design.

The design features that play significant roles in the design of a final product are: aesthetics, economics, functionality and originality. The functionality of furniture is based on its comfort, safety and usefulness. And these qualities of comfort, safety, and usefulness are related to the anthropometric characteristics of the user and the suitability of materials used in furniture design.

2.2 METHOD USED

In order to calculate optimum furniture dimensions anthropometric measures were taken from a total of 55 children under age group of 2.5 years to 4.5 years were used. A total of 14 different measurements were made while the children were the in sitting and standing positions. In calculating the optimum dimensions of the furniture, dynamic or static anthropometric measures, minimum and maximum values, and also the function of the furniture were taken into consideration. All of the furniture was divided in to two groups according to reach and volumetric function based on the main criteria of anthropometric design.

The formula for calculating the optimum furniture dimension is a form of normal distribution in probability theory. The general equation for maximum and minimum is calculated.

Maximum values were calculated by: Furniture dimension = $X + (SD \times Z)$

Minimum values were calculated by: Furniture dimension = $X - (SD \times Z)$

Where X = Mean or Expectation of distribution

SD = Standard Deviation

Z = Constant corresponding to assumed confidence interval

Here we are taking the normal distribution with a confidence interval of 95% ,i.e., the chances of any error occurring in our design is limited to 5% and is verified too. Thus the value of Z is taken as 1.96.

Calculations of the depth, height and breadth of the furniture and equipment which are considered to be used rather frequently by children were done. Anthropometric data of children were used when calculating the measurements.

3. DESIGNS

3.1 TABLE DESIGN

- Table depth (for one person) (max, value) = Forward elbow reach (X) + (SD x Z)

Table depth (for one person) (min, value) = Forward elbow reach (X) - (SD x Z)

- Table breadth/ width (max. value) = Buttock-knee depth (X) + (SD x Z)
- Table height (max. value) = $0.41 \times (\text{total height (X) + (SD x Z)})$

NOTE: The minimum values are obtained by connecting the standard deviation by minus sign (-) instead of plus sign (+).

Fig 1: Table Depth and Table Height

Fig 2: Table Width

Sample calculation (All dimensions are in cms)

Table height max value (age group 2.5 years) = $0.41 \times (108.009 + (1.96 \times 4.7)) = 48.060$ cm

3.2 CHAIR DESIGN

- Chair depth (max. value) = $0.6666 \times (\text{Buttock-knee depth } (X) + (SD \times Z))$
- Chair breadth/width (max. value) = $\text{Hip breadth } (X) + (SD \times Z)$
- Chair height (max. value) = $\text{Sitting height } (X) + SD \times Z$
- Seat rest height (max value) = $0.75 \times (\text{upper part while sitting}(X) + (SD \times Z))$
- Hand rest height (max value) = $0.25 \times (\text{upper part while sitting}(X) + (SD \times Z))$

Fig 3: Chair Height and Chair Depth

Fig 4: Chair Width

Sample calculation

Chair height (max value) (age group 2.5 years) = $(26.4 + (1.96 \times 1.0274)) = 28.413$ cm

3.3 DESIGN OF BEDS AND BUNKS

- Bed breadth (max. value) = $2.5 \times ((\text{Buttock knee depth } (X) + (SD \times Z)) - (\text{Hip width } (X) + (SD \times Z)))$
- Bed length (max. value) = $\text{Stature } (X) + (SD \times Z) + (\text{pillow})$
- Bed height (min. value) = $\text{Sitting height } (X) + (SD \times Z)$
- Bunk height (max. value) = $(\text{height of lower part while sitting } (X) + (SD \times Z)) + (\text{height of upper part while sitting} + (SD \times Z))$

Fig 5: Bed Length and Bed Width

Fig 6: Height of Cot from Ground and Bunk Height

Sample calculation

Bed length (max value) for age group 2.5 years = $108 + (1.96 \times 4.7) = 117.2 \text{ cm}$

3.4 DESIGN OF TOILET ACCESSORIES

- Water Closet pan height (max. value) = Sitting height (X) + (SD x Z)
- Wash basin height (max value from ground) = height of leg while standing(X) + (SD x Z)
- Distance of person to tap(max value) = (Forward reach of arm(X) + (SD x Z))

Fig 7: Height of Water Closet

Fig 8: Wash Basin Details

Sample calculation

Water Closet pan height (max value) = $27.8727 + (1.96 \times 1.89) = 31.577 \text{ cm}$

3.5 DESIGN OF CLASS ROOM UTILITIES

- Cupboard height/shelf height (max. value) = Eye height (X) + (SD x Z)
- Switch height (max value from ground) = $(0.75 \times \text{total height}(X) + \sqrt{2} \text{ forward reach of arm}) + (1.96 \times (1.75 \times \text{SD}_{\text{total height}} + \sqrt{2} \text{SD}_{\text{forward reach of arm}}))$
- Black board height (max value)= $0.44 \times (\text{Total Height (X) + (SD x Z)})$

Fig 9: Height of Shelf

Fig 10: Height of Switch Boards

Sample calculation

Shelf Height (max value) = $93.1919 + (1.96 \times 1.67) = 96.4641 \text{ cm}$

The measured anthropometric details along with their mean values standard deviation, error, margin of error, intervals are presented below along with all the maximum and minimum values of the design for age group.

4. RESULTS

The various furniture dimensions were calculated using the formulae mentioned earlier and a comparison between the existing range of furniture dimensions and the obtained value was made as shown in the table below.

Table 1: Comparison between Existing and Calculated Values

Parameter	Existing Value (Cm)	Calculated Value (Cm)
Table depth	20-40	23-36
Table width	25-35	28-39
Table height	40-48	34-48
Chair depth	15-20	19-26
Chair width	33-37	19-37

Chair height	24-28	24-32
Seat rest height	37-50	18-54
Hand rest height	5-20	6-18
Bed width	50-80	52-62
Bed length	80-120	83-112
Bunk height	-	49-104
Cot height from ground	20-30	24-73
Cupboard height	124-145	74-96
Switch height	75-90	95-153
Blackboard height	110-130	100-128
Water closet pan height	24-28	24-31
Wash basin height	45-52	56-62
Distance of tap from person	20-30	26-46

The minimum value of calculated furniture dimension corresponds to the age group of 2.5 and the maximum value corresponds to the age group of 4.5.

Here we see that there are variations in the existing values of furniture dimensions and the calculated values. These variations are mainly due to the fact that here, the furniture dimensions are calculated according to Indian Standards by considering the anthropometrics of the Indian children. So for the safety and comfort of the students in the Early Learning Centre, the furniture dimensions should be designed according to the calculated values.

5. CONCLUSIONS

The design guideline for an ELC has been prepared. By referring this guideline, a safe, efficient and child friendly ELC can be designed which is fully functional in design, cost effective to operate and environmentally safe and secure .

The design guidelines have been prepared based on the identified parameters from the literature studies of ELC of other countries.

The prepared guidelines are purely based on Indian Standards so that Indian children can use these living spaces, working spaces, furniture and other equipment in safe as well as comfortable manner. And hence, the center will provide consistent, high quality care to meet the needs of the active, continually developing child.

Abstract. Emotion Recognition (ER) systems is very much important for interpersonal relationship. Emotions are developed by some physiological changes. The straightforward of this effort is to discover the competence of language and facemask elements to deliver the feeling exact information for enhancing the Human-Machine interaction. The techniques and systems used in emotion detection may vary depending on the features inspected. Since both these features complement each other, combining them results in higher performance in terms of accuracy of 94.734%. The proposed system was tested on ENTERFACE'05 database and real time video. For Video, Speeded Up Robust Features (SURF) and Gabor features are used.

Keywords- : Emotion recognition; Support Vector Machine (SVM); prosodic features; SURF and Gabor Features; Extraction of energy contour; Extraction of pitch contour

1. INTRODUCTION

Emotion theory is related with organization of some aspect of human behavior or performance [1]. It enables us to make predictions about the behavior or performance. Components of emotion include (i) Cognition (ii) Physiological (iii) Expressive (iv) Motivation and (v) Feeling. Recently, emotion recognition in human - computer interaction studies (HCI) is one of the topics that researchers are most interested in. To have a human like interaction, machines should be trained in such a way that it can identify the faces and recognize the emotions. During the training process of a machine the main challenge comes during the natural interface with the user. ER is very important because the meaning of the message can be altered by the emotions. Emotions are transparently identified from the face, body gestures, sound, and intensity of the voice. Hence, researchers have started to shift their studies toward spontaneous facial expression by fusing the speech expressions [2-4]. The fusion of features is performed either at the decision level or before classification. Multimodal approaches by combining the mode of interactions results in enhancing the understanding level and results in an efficient ER system in terms of better performance and robustness.

The summary of this work is prearranged as follows. Section II deals a review of related works and methodology used in this work. The proposed work is also presented in this Section for facial ER system, Speech ER system and multimodal system.. Section III deals the Results and discussions, and final section concludes the paper.

2 MATERIAL AND METHOD

2.1 Related Works

Emotional expression is one of the basic expressions of the human. It motivates an action by adding a meaning and richness to the human experience. Basic emotional theory states that almost all ER system works on the universal emotions. However, in majority of real-life situations the system fails as it is different from the acted emotions. Existing studies about ER systems from video are discussed in this section which includes following dimensions (i) facial system, (ii) acoustic system and (iii) combined facial and speech system.

2.1.1 Facial ER system

Few other works using facial ER system employed methods such as optical flow technique [4] [5], [6][7], appearance model [8] and local parameterized models [9]. OF is also used by Rosenblum [10] [11] [12] to measure the facial region with Radial Basis Function (RBF) network as a classifier. Otsuka and Ohya [11] [13][14] used the OF to calculate the 2D Fourier transform coefficients which is applied to Hidden Markov Model (HMM) to classify the expressions [17].

2.1.2 Multimodal ER system

Extensive research was performed based on ER by using either facial or speech features in the past, now the researchers have moved towards fusion of audio and visual data for an efficient ER system.

Decision level fusion [23] separately means every unimodal structure and combines the result at the end. For predicting the emotions effectively two unimodal systems are shared at the better dimension using facial, acoustic, facial, features. Few other studies were made on emotion recognition using facial features [24-25], speech features [26-29] and with combining both features [30-33]. Based on the above studies, it is observed that design of a multimodal system has significant advantages in enhancing human machine interaction. With this motivation, fusion of features (facial and speech) is attempted in this work to enhance the human-machine interaction. The proposed system in this study with the fusion of facial and spectral features is providing better results in terms of accuracy. The details are elaborated in the next sections.

2.2 Methodology

In this work, a multimodal scheme for programmed ER is proposed. Figure. 1 depicts the whole process of machine learning emotion recognition used in this study. The stages include (i) Obtaining emotional face and speech database (ii) Feature selection and extraction (iii) Classification. Initially, two unimodal systems are developed by exploring the facial and speech features. The description of these features is elaborated in the following sections. Datasets used is ENTERFACE'05 database. In addition, the developed system was tested with real time video data.

Figure. 1 Machine learning approach for emotion recognition system

2.2.1 Feature Extraction

2.2.1.1 Prosodic Features

One of the significant features of the speech is the energy contour. It is used to differentiate the unvoiced region and voiced region of the speech. Vowel sound mainly serves high energy contour. Since speech signal is stationary in nature, it has to be segmented by multiplying with a window function. Most preferred window for segmenting is hamming window because it gives the higher weight to middle samples. After segmentation, squaring is done which yields the energy signal. These energy values are plotted against the time domain to get the energy contour. Fundamental frequency of the speech signal is referred as pitch. Pitch contour mainly refers to a curve that track the pitch in a given speech signal. It includes variety of sounds utilizing multiple of pitches and also relate to the frequency function at one point to a later point. Resonance frequency of human vocal tract is referred to as formant.

2.2.1.2 Spectral Features

Spectral features are mainly used to capture the information based on movement of articulate, shape and size of vocal tract. In the proposed work, MFCC features are used to extract the emotional information. They are the coefficients of Mel Frequency Cepstrum which is derived from power spectrum. In this work for each audio file 13 coefficients are derived. After taking the mean and variance of these coefficients it is fed into the feature extraction part.

2.2.1.3 Gabor Features

Properties of image are mainly defined by the features extracted out of it, which is then used for the identification of the image in next phase. Gabor filters are used in this work to extract the features with 5 scales and 8 orientations [34, 35].

Gabor wavelet is defined as

$$\Psi(Z) = \frac{P_{a,b}^2}{\sigma^2} \exp\left[-\frac{P_{a,b}^2 Z^2}{2\sigma^2}\right] [\exp(iP_{a,b}Z) - \exp(-\frac{\sigma^2}{2})] \quad (1)$$

Here $z = (x, y)$ which is the input image, a denotes the orientation and b denotes the scale of the Gabor filter. $P_{a,b} = P_b e^{i\phi_b}$ Where $P_b = P_{max} / f_b$ and $\phi_b = \pi b/8$. P_{max} gives the maximum frequency and the spacing factor is termed by f .

Figure 2. Real and imaginary part of Gabor Wavelet

Gabor filter mainly has two parts: the real part and imaginary part. The real part is transformed to get the magnitude feature and the phase feature is derived from the imaginary part. For every image there are 40 Gabor features. Computation of Gabor wavelet features is more complex and also the redundancy is high due to the convolution of Gabor wavelet with facial images. Statistical parameters are computed such as mean, standard deviation over feature vectors to reduce the problem of computational complexity. The real and imaginary part of Gabor wavelet used is shown in Figure 2.

2.2.1.4 SURF Features

The SURF detector is based on Gaussian derivative filters which is used to locate the features. By convoluting the basis image with the factor of the Hessian (DoH) matrix (Equation 2). The metric obtained by this method is further divided by the Gaussian's variance, σ^2 , to normalize its response:

$$DoH(x, y, \sigma) = \frac{G_{xx}(x, y, \sigma) \cdot G_{yy}(x, y, \sigma) - G_{xy}(x, y, \sigma)^2}{\sigma^2} \quad (1)$$

$$\text{where } G_{ij}(x, y, \sigma) = \frac{\partial N(0, \sigma)^2}{\partial i \cdot \partial j} \cdot \text{image}(x, y) \quad (2)$$

By blurring the image the Gaussian filters are removing the noisy data, hence many feature detection schemes rely on Gaussian filter. SURF beats the existing techniques in terms of fast performance, robustness, repeatability, and distinctiveness. The algorithm mainly has two parts (i) Detector and (ii) Descriptor. Key point in the input image is located by the detector whereas feature extraction and the construction of the feature vector are performed by descriptor. For detecting the key points it is necessary to construct the scale space which is commonly a pyramid scale space. For describing the features of key points SURF uses the response of Haar wavelets. These wavelets are preferred because of its robustness and less computation time. In order to extract the descriptor, first step is to construct a square region which is centered at the key point. This region is then split into smaller sub-region, and every sub-region response of Haar wavelet is computed. To obtain the first entries of the feature set, wavelet responses are summed up, and for the intensity changes absolute values of the responses are calculated. The results of the SURF features extracted for the ENTERFACE'05 database is shown in Figure 3.

Figure.3 Extracted SURF features

For classification SVM is used in this work which is a classification prediction that use theory space of a direct roles in a extraordinary dimensional feature vector [36]. Using SVM, it is possible to map linearly non-separable features into linearly separable filters[37]. In this work, RBF kernel and polynomial kernels were used and the results are compared. The next section elaborates proposed methods for ER system using facial features, acoustic features, and combined features.

2.3 Description of proposed multimodal system

2.3.1 Facial Emotion Recognition System

The projected work for the facial feeling recognition is depicted in Figure 4. Three key points in the facial ER systems are detecting the face, extracting feature and the classification. The response given to the detection stage in the shape of an image, so that the video input data is converted into frames.

Figure 4. Proposed system for Emotion Recognition using facial features

Then, this algorithm [38] is used over every framework to get the region of interest. The output of the face recognition and the ROI detection is shown in Figure 5.

Figure 5 Face recognition and ROI detection [23]

In the next stage, Algebraic features cruel and standard deviation were calculated for respectively responses of the Gabor filter. Next SURF features are extracted from the entire face. To lessen the dimensionality dilemma, mean of the features were calculated which caused in the feature vector length of 64. Classification was carried out using SVM with four different emotions: anger, disgust, fear and happiness.

2.3.2 Speech ER system

Figure .6. Proposed system for Emotion Recognition using speech features

The proposed system for emotion recognition using speech is depicted in Figure 6. Recognition of emotion from speech, spectral and prosodic features is employed. Studying the spectral behavior, MFCC is explored while pitch, energy and formants are utilized to find the prosodic information which is shown in Figure 7.

Figure 7. Extraction of Pitch Contour

2.3.4 Extraction of energy contour

Next feature extracted is the energy contour, and the steps for extraction are described in Figure 8. The dissimilar steps in discovery the frequency are given below (i) Pre-emphasize of input speech signal and normalization to 1 and -1 amplitude (ii) Segmentate of voice signal by getting after applying hamming window (iii) Removal of DC values using Butterworth high pass filter (iv) Computation of the logarithm of the spectrum for the visibility of all the values. Based the proposed systems for emotion recognition using facial and speech features, a multimodal system can be designed as shown in Figure 10.

3. RESULTS AND DISCUSSIONS

Initially face ER system was developed and two features are extracted namely Gabor and SURF. The method of extraction of these features is explained in section II. As an initial step Gabor features are stemmed from left eye, right eye and mouth and fed to the classifiers. The accuracy obtained for Gabor features by polynomial kernel is 68.42% and RBF kernel is 47.36%. As a second step, the Face system is made by SURF features. It gives accuracy as 63.15% for polynomial kernel and 47.36% for RBF kernel.

As a third step, SURF and the Gabor features are combined which gives improved accuracy as 66.66% using RBF kernel and 90.47% using polynomial kernel. It was observed from the results that polynomial kernel outperforms well for the classification using combined features (Table. 1). Next stage after face ER system, speech ER system was developed. The MFCC features of the speech signal is extracted which yields a system with an accuracy of 63.15 % for polynomial kernel. For speech system, classification using RBF kernel is giving better results using prosodic features whereas polynomial kernel gives better results for spectral features [42]. Fusion of these features increases the overall performance of the system in terms of accuracy using polynomial kernel upto 84.21%. Table. 1 gives the accuracy of different systems and its comparison by using different kernels. From the Table 2, it was observed that the data set of DEAB is giving the highest accuracy of 94.73% compared with unimodal face and speech ER systems. The details of fusion of data considered are elaborated in Figure 11.

Table 1 Comparison of two kernels

Features	Efficiency by RBF kernel	Efficiency by Polynomial
Prosodic features	89.47%	78.94%
Spectral features	47.36%	63.15%
Prosodic + Spectral features	73.68%	84.21%
SURF features	47.36%	63.15%
Gabor features	47.36%	68.42%
SURF + Gabor features	66.66%	90.47%
Face system + speech system	89.47%	94.73%

Table 2. Accuracy results for multimodal system with various fusion combinations

Training Data	Testing Data	Face system	Speech system	Multimodal system
ABCD	E	84.21%	73.63%	89.47%
BCDE	A	78.94%	73.63%	84.21%
CDEA	B	78.94%	78.94%	89.47%
DEAB	C	90.47%	84.21%	94.73%
EABC	D	84.21%	78.94%	90.47%

Table 3 shows the confusion matrix of face system. The overall performance for this system is 90.47%. Anger, fear and happiness are correctly classified whereas the disgust is often confused with anger. Although, disgust is correctly classified by 90.42% however, almost 9.523% misclassification is happening for this emotion.

Figure 11. Combinations of Training and Testing data used in the proposed system

Table 3 confusion matrix for face ER system

	Anger	Disgust	Fear	happiness
Anger	100%	0	0	0
Disgust	0	100%	0	0
Fear	0	0	100%	0
Happiness	5.263%	0	0	94.736%

Table 4. Confusion matrix for speech ER system

	Anger	Disgust	Fear	happiness
Anger	100%	0	0	0
Disgust	9.523%	90.47%	0	0
Fear	0	0	100%	0
Happiness	0	0	0	100%

Table. 4 shows the confusion matrix of speech system. The overall performance for this system is 84.21%. Anger, fear and disgust [43] are correctly classified whereas the happiness is often confused. Happiness is correctly classified by 84.21% but it is misclassified with anger and disgust by 10.52% and 5.26% respectively.

Table 5. Confusion matrix for multimodal ER system

	Anger	Disgust	Fear	happiness
Anger	100%	0	0	0
Disgust	0	100%	0	0
Fear	0	0	100%	0
Happiness	10.52%	5.26%	0	84.21%

Table 5 shows the confusion matrix of proposed system. The general performing for this system is 94.736%. Anger, fear and disgust are correctly classified whereas the happiness is often confused. Happiness is correctly classified by 94.736% but it is misclassified with anger by 5.623%. The three systems are then tested for real time video data set collected (Figure. 12). The two emotions happiness and anger are considered and classified by using SVM classifier. It is possible to obtain 80% accuracy using the proposed multimodal system. To increase the quality of the system, number of training data is to be increased which is the future scope of the work. The result of the real time data classification is given in Table 6. The given system is associated with the current methods and the results are given in Table 7.

Figure.12 Detection of ROI from real time Video

Table 6. Real time emotion classification

Speech	Accuracy
Speech system	55.55%
Face system	77.7%
Multimodal System	80%

Table.7 Comparison with existing method

Previous Studies	Maximum Accuracy Obtained	Proposed Method	Accuracy
Face System by Gabor Features	85.71%	Face System by Gabor + SURF Features	90.47%
Speech System by Spectral Features	80.32%	Speech System by Spectral and Prosodic Features	84.21%
Multimodal system by Morphological and Spectral Features	93.62%	Multimodal System	94.73%

4 CONCLUSIONS

A multimodal framework on ER system is proposed in this work. Then a combined system was developed, and results reveal that there is a marginal improvement in the performance with 94.73%. It was observed that polynomial kernel outperforms well in the classification stage of all the proposed systems. The proposed system was tested on real time video and it is possible to obtain the accuracy of 80% which can be enhanced the quality and number of training data. Feature level fusion is employed in this work and it can be extended to physiological signals with real life scenario instead of staged performance. Gestures hear beat and skin conductivity analysis may also give a better system [39]. Using advanced machine learning techniques and using deep convolutional networks it will be possible to overcome the limitations mentioned in the proposed work [40, 41].

H Base Repository Design for Sensor Devices Generated Big Data

Gunasekaran.S, Palanivel Rajan.D and G. Ravikumar

Abstract

Internet of Things (IoT) is an emerging technology, in which reliable information are collected from millions of RFID/ sensors and this data can be quickly transformed into a database for storage purpose. In IoT, data that are generated by some devices such as RFID, sensors and mobile phones have to be analyzed in real-time. The sensory data are plenty in amount and unstructured in format. Consistency and rapid transaction of the data generated by the IoT devices become a vulnerable task. This paper focuses the solutions for these problems using HBase Database model in Cloud environment. This paper focuses and proposes a RFID/sensor integrated repository model using HBase which is the most ubiquitous NoSQL database storage system in the modern era. Primarily, it devises a data repository schema that can effectively integrate and store the heterogeneous IoT data sources, such as Medical Sensor Data, GPS Information and RFID values. Secondly, it proposes an effective HBase schema to maximize query speed and uniform data distribution over data server. This paper adopts HBase in a cloud environment, including random read or write capability for real time access and fault tolerance. In this paper, Apache cloud stack is used to provide Infrastructure as a service to farm the virtual machines and to provide platform as a service (Paas). HBase uses master-slave architecture where master keeps the Meta information about all the slave region servers. HBase delivers atomic read, write features, and provides Write-Ahead Log across the cluster to support automatic failure management. Through a series of experimental results for measuring query performance and query response time, it shows that HBase optimize the read and write transaction of Large data set and provide optimized query performance. It supports the best load balancing policies and achieves scalability, consistency and automatic failure management. The proposed HBase Repository was perform better in terms of storage, data distribu-tion and response time.

1. Introduction

Internet of Things is an emerging trend in modern internet which links any real world objects with the Internet. IoT allows these objects to exchange and collect data and it also enables these objects to control and sense remotely over a current system foundation. It makes a possibility for direct coordination of the physical world into PC based frameworks. The advancement of Internet of Thing and quick improvement of innovations creates a wide spread of the association of thing and it will demonstrate a lot of generation of information that are to be put away, got to and handled. Distributed computing goes about as a front end to acquire the Internet of Things.

Cloud computing is a model for enormous information stockpiling and investigation. The incorporation of IoT and distributed computing permit detecting gadgets and incredible handling of detecting information stream (i.e.) sensing data are stored through cloud computing and used automatically for smart actuation and monitoring with smart devices.

Radio frequency utilizes electromagnetic fields to distinguish labels and track articles appended to the labels. RFID is primarily centered on putting away and recovering information through electromagnetic transmission (Radio Frequency). Today, RFID has been generally utilized/applied in store network following, library books following,

baggage attaching in aircrafts, shopping center to gather things and toll accumulation so on [3]. RFID consists of two main components: Tags and Readers. RFID tags can operate in three frequency ranges: ultra-high frequency, high frequency, and low frequency. Their range is 850-950 MHz, 10-15 MHz, 30-500 KHz respectively. Companies and organizations using Internet of Things for different purposes. These technologies, monitoring physical objects. It requires necessary components to qualify the communication between devices and objects. Hence, uniquely identify each object. Using these unique objects, reporting/monitoring data in real time is making quicker, more accurate in nature.

1.1.Integration of RFID and sensor

RFID and sensor systems are both significant components in IoT. Sensor system is typically used to detect and screen physical conditions through some detecting components. Sensors can give considerably more data about the estimation of temperature, mugginess, weight, vibration and power. Here RFID label gathering detected information and give recognizable proof number to every datum than per user peruses information utilizing RFID labels. There are a few RFID labels

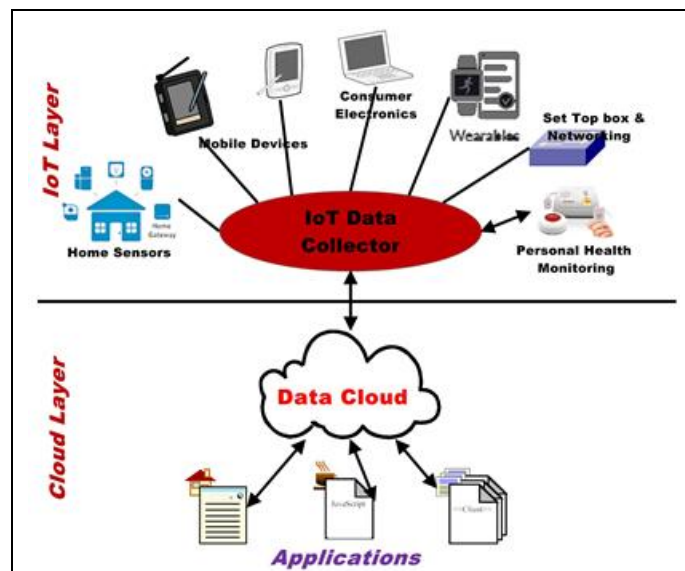

Fig. 1. IoT in Cloud Computing Era.

Coordinated with sensors to detect information and its ability work. Mongrel lease RFID detecting applications incorporate checking physical parameters, programmed item hurtful specialist recognition, non-intrusive observing and alter identification [15].

IoT is about the gadgets that coordinated to the web to play out the procedure and administrations, which bolster our fundamental needs, for example, financial aspects, wellbeing, horticulture, retailing, and condition, dress, fuel and synthetic compounds, sports and games and furthermore improves money related pay. Thus, cloud computing goes about as a front end apparatus to get to Internet of Things. Cloud computing is an Internet based computing (on demand computing) that provides resources for computers and some devices. Cloud computing provides users to store data in storage framework and access the data using cloud servers. Since sharing of resources can improve economies of scale. It can use Google apps "Picasa "to store your picture to the Internet. So, the picture can load from Internet through those applications at any time.

The above figure 1 shows that multiple devices that are combined in IoT and stored/processed IoT related data into cloud environment. The ascent of distributed computing and cloud computing intended for dispersed frameworks. It can fill in as information stores like NoSQL databases, for example HBase or Cassandra.

1.2. Modern internet world and HBase

The necessity of big data comes from the big companies like Google, Amazon and Facebook. The storage technology is based on cloud computing and it allows effective management of big data. For the purpose of analysis of big amount of data which is in unstructured form are difficult to process billions records which contains millions of data information. Apache Hadoop is an open source software to store large scale processing of data sets and scaling up these data sets into single server. HBase is the Hadoop database which can provide real- time access to the data and powerful scalability. HBase was designed based on the Big table which is a database was launched by Google. HBase aims at storing and processing Big Data easily. More specifically, it uses a general hardware configuration to process millions/billions of data. HBase is an open source, distributed, has multiple versions, and uses the NoSQL database model. It can be applied on the local.

HBase is column oriented key/value data store building on the top of the Hadoop file system. It is a data model designed to allow quickly random acquire for large amount of structured data and provide powerful data consistency on read and write, that distinguishes from other NoSQL databases. The architecture of HBase uses master nodes to control region servers that are processed and distributed as a part of data tables. It internally uses hash tables and provide random access, and also produce faster lookups for larger tables. The relationship between Clouds computing vs. big data, Relationship between IoT vs. Big data, has been discussed in below.

1.3. Relationship between IoT and Big data

Big data and IoT are the same both are referred large amount data. In IoT paradigm, the enormous amount of network sensors are embedded into devices. Such devices establish in different fields may collect various kinds of data, such as logistic data, geographical data, astronomical data, and environmental data. Cisco estimates that 50 billion objects and devices will be connected to the Internet by 2010. More devices generate more data. A new report from ABI research estimates that data captured by IoT-connected devices exceed the level of 200 Exabyte's in 2014. The annual total rate is forecast to grow sevenfold by the decade's end, surpassing 1,600 Exabyte's or 1.6 zeta bytes in 2020. For evaluating the enormous amount of data, we can use Big Data which can bring analytical information in real time. Once the data is received, next consider the platform to store the huge amount of IoT data. Nowadays, many companies use Hadoop and Hive to store big data. But in IoT, NoSQL databases are more suitable to process and store the data.

IoT is to link different objects in the real world, such as RFID, sensors, etc. to realize information exchange and to make them cooperate with each other to complete an ordinary methodology. It is deemed as the extension of the Internet of Things and is an important part of the future research and internet world. It is mainly characterized with that it accesses every data in the physical world such that the data can be addressed, controlled, and communicated with large amount of data. These data/ information's are tracked by IoT technologies using RFID Readers/Tags and sensors. Data generated by the devices and first gathered, preprocessed and then sent to the cloud environment, which is built based on the data storage framework using the Hadoop system. In order to improve the performance of data storing and accessing, all types of data are stored in different places MySQL (SQL database), MongoDB and HBASE (NoSQL database). The proposed work use HBase database for storing/retrieving data in an efficient manner.

The Section II presents the related work. Section III explains the overall proposed system and designs the implementation details. Section IV explains the experimental setup and HBase performance test. Section V displays the experimental results compared with HBase, including the comparisons of MySQL and Mongo DB. Section VI presents the concluding remarks and also suggests some future enhancements.

2. Related Work

The Internet of Things has given a promising opportunity to assemble incredible applications by holding developing omnipresence of Radio Frequency Identification and remote sensor gadgets. IoT information can be created very quickly, the volume of information can be tremendous and the kinds of information can be different. This information stockpiling system can join and ex-pand various databases. The Hadoop store and oversee information by using various kinds of information gathered by sensors and RFID peruses [1]. Be that as it may, it has numerous confinements on handling a lot of unstructured information, for example, IoT created huge information, utilizing existing social database technologies.

In this sense, the IoT created information to be put away in an archive situated database for example MongoDB [2]. Over the most recent few decades, radio-recurrence ID technology has been generally utilized in barrier, fabricating, coordination, condition, medicinal services, farming, retail, flying, and data advancements, including RFID, sensors, worldwide situating frameworks, and mechanized actuators has of late been extended to creation the executives, quality management calculated administration, utility administration, and stock administration in different enterprises [3].

In the assembling business, for instance, when a RFID tag is joined to individual parts or items, their area data can be gathered continuously, in this manner empowering adaptable creation arranging and shipment request position. Moreover, if quality issues emerge, their causes can be examined utilizing relating sensor information gathered from the important assembling office to pinpoint the wellspring of the quality issues. In the sustenance organization, security the board of short-lived nourishment has been extended from creation to transfer. [14]. RFID frameworks can be utilized to record and store information through electronic gadgets (EPC) utilizing radio frequencies to get to a few programmed administrations, for example, information the board, gadget and control the executives. It is utilized as a remote convention for access correspondence be-tween different sensor gadgets need solid and information rate transmission, control utilization are low inside a comparatively little separation and a more extended battery life. The gathered data/information can be made accessible on Cloud Computing to utilize remote access. Cloud computing alludes to task allocation/preparing needs applications, stages and foundation, and utilization of shared registering assets over the Internet [5]. RFID and sensor systems are both significant segments of inescapable computing. The Sensor is generally used to detect and screen information while incorporating sensor and RFID it can give significantly more data about specific information [15].

The term 'NoSQL' to the new information world doesnot sem to be exact information model of social databases. By giving up a portion of the properties, (for example, ACID exchange's properties) of the social database model, NoSQL databases can accomplish higher accessibility and adaptability, which are basic requirements for enormous information handling. Like social databases NoSQL databases don't need a fixed pattern with limitations and pre-characterized information structures to be deduced in a beginning time of database plan [11].

Leavitt [20] discussed that NoSQL databases won't substitute social databases, which are progressively full grown and as of now broadly introduced, soon. Notwithstanding, for some particular purposes, for example, taking care of unstructured massive information notwithstanding requiring an abnormal state of versatility, NoSQL databases will be a superior decision. Today, a wide scope of assortment of NoSQL database items available, which are worked to fit explicit purposes. Thusly, NoSQL information bases will have

their very own specialties, which are notwithstanding extending quickly, as indicated by the developing requirements for huge information expert accessing in different fields. Sooner rather than later, NoSQL proponents and merchants will concentrate on building up the reasonable application and the board instruments.

Not just SQL (NoSQL) databases give various instruments instead of the forbidden connections of a relational database for the information stockpiling. For the most part, in view of the information model, NoSQL databases can be isolated into four feline categories, for example (1) segment, (2) key-esteem, (3) record and (4) chart, in which segment arranged NoSQL is most like the conventional social database [17]. Van der Veen et al. [4] have talked about the potential outcomes to utilize NoSQL databases, for example, Cassandra and MongoDB in huge scale sensor net-work frameworks. The outcomes demonstrate that Cassandra is the best decision for enormous basic sensor application; MongoDB is the best decision for a medium estimated insignificant sensor application. Then again, MongoDB has a normal performance when utilizing virtualization [21] conversely; read performance of Cassandra is vigorously influenced by virtualization. Nyati et al. [22] presented the addition/scanning performance of MongoDB for MySQL in a solitary machine, showing that MongoDB beat than MySQL. It can't utilize basic key-esteem stores for the purposed of RFID/sensor information vault. The RFID/sensor information storehouse is utilized for the most part for occasion following or search inquiries decently than a segment shrewd conglomeration as works in OLAP, implying that section situated databases are not desirable over document databases either. Among report databases and it is the most well-known NoSQL database as per [23].

All printed material, including text, illustrations, and charts, must be kept within the parameters of the 8 15/16-inch (53.75 picas) column length and 5 15/16-inch (36 picas) column width. Please do not write or print outside of the column parameters. Margins are 3.3cm on the left side, 3.65cm on the right, 2.03cm on the top, and 3.05cm on the bottom. Paper orientation in all pages should be in portrait style.

Information size in information stores has expanded systems administration and business requests. In this way expanding expense of assets required as far as system and space use. For comprehensible content, it stores terabytes of information and it is profitable to pack the information to acquire critical investment funds in required crude stockpiling. Though segment situated databases spare the information by gathering in segments. HBase is one of the most unmistakable NoSQL sections arranged information store. In this paper, cloud based HBase is presented with regards to section situated database frameworks [13]. Information is detonating at a stunning rate. By 2012, the advanced universe of information develops to 2.72 Zetta bytes (ZB) and twofold like clockwork to arrive at 8ZZB by 2015. In 2018, Big Data innovation and administrations market develops at a 26.4% compound yearly development rate to \$41.5 billion. For point of view which is likeness 18 mil-lion Libraries of Congress. There are billions of associated gadgets running from PCs and advanced mobile phones to sensor devices are traffic cams and RFID perusers produce this field of complex organized and unstructured information [18, 19].

HBase distributed computing foundation is constructed, which store and procedure huge information [6]. Cloud database can deal with an extremely huge measure of information and number of database gets to and it underpins semi organized and unstructured information alongside the organized information. It is a cloud database which is an open source, non-social, circulated database [7-9]. Two different fragments of cloud database focuses were presented, for example HBase and Cassandra [12]. Highlights/Capabilities are looked at for different NoSQL databases like Dynamo DB, Redis, Voldemort, Cassandra, HBase, Mongo DB, Simple DB, Couch DB, BigTable, and Apache Jackrabbit [10]. Review of distributed computing and huge information advances dis-cussed in [8]. In this paper Hadoop-HBase gives distributed and parallelized information preparing and investigation of petabyte (PB) scale informational indexes.

Dispersed Semantic Web information the executives talked about utilizing cloud and social database advancements spoken to by HBase and MySQL [24-25].

3. PROPOSED SYSTEM

In this system HBase is adopted in a cloud environment, including random read/write capability for real time access and fault tolerance. IoT consist of many devices like sensors, mobile phone and RFID so on. The amount of objects rises every day and the manner in which data is collected between the objects is altered. Continuously, RFID / sensors engaged in IoT generate an enormous quantity of information and data. Cloud computing is an optimal method to help this quantity of data and use HBase to operate many facilities on top of the HDFS. In our proposed architecture, cloud computing is used to integrate IoT such as RFID/Sensor as shown in the figure 2. Cloud computing also provides access to all resources such as mobile devices, sensors, and tags for RFID.

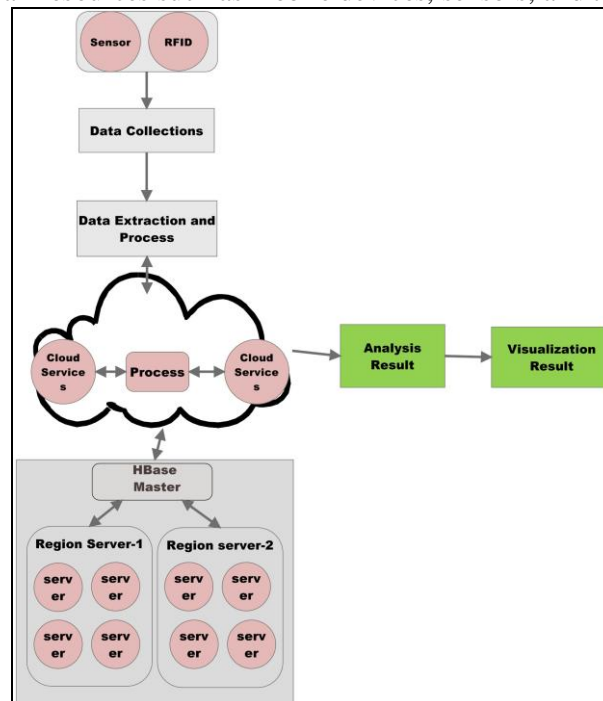

Fig. 2. Proposed System Architecture model with cloud integration.

HBase infrastructure is built using several data together based on cloud computing. Apache cloud stack is used to provide Infrastructure as a service to farm the virtual machines and to provide Platform as a Service (PaaS). HBase cloud data storage is used to support data storage and access. Cloud computing offers a financially savvy method for giving offices to handling and for calculation of huge information and furthermore bolster huge information advances.

3.1. RFID

RFID is an automated technology; it consists of TAGS and READERS. IoT refers to uniquely identify objects and their virtual presentations of objects, add their virtual representation in an internet. RFID-frequency identification is often seen as a prerequisite for the Internet of Things.

- RFID Tags: RFID Tag consists of identification number (ID) for uniquely identified data.
- RFID Reader: RFID Reader is the communication tool with any tags in its read range.

Information gathered from the sensors are typically kept in a type of information stockpiling arrangement. Anyway the quantity of sensors expanded, the measures of information likewise increment. It turns into a non-inconsequential assignment to constantly store it. Conventional sensor information stockpiling arrangements teach putting away information for just a specific time of times. For example assume in a Retailing Application, a retailer with 30,000 stores sells 1,00,000 things per day for each store. Expect it record everything development with a tuple of the structure: EPC tag, area, time where EPC tag is a Code that particularly recognizes everything. On the off chance that everything leaves just 20 follows before leaving the store by going through various locations and it will create at any rate 3000 million tuples every day. Supervisors solicit questions on the length from ways and inquiries are (1) Checklist the normal timeframe of realistic usability of milk items in 2015 (2) Calculate the interim that it took dairy items to move from capacity to the rack (3) Finally to inspect the last counter list in 2015 March.

Because of this reason, it has made a circulated and scalable information stockpiling subsystem to spare sensor information until they are investigated. Open source No SQL databases give productive diverse to huge measure of sensor information. For this situation cloud based HBase database is utilized, it is a prominent open source NoSQL database. HBase is a segment situated database which backing for putting away detected information. It gives simple versatility, high accessibility, and top-level execution. It additionally enables us to effortlessly scale the database for certain situations when an enormous number of sensors utilized. Colossal volume of sensitive information stream over the cloud condition for putting away, analyzing, and produce the information and authority over the physical world utilizing HBase.

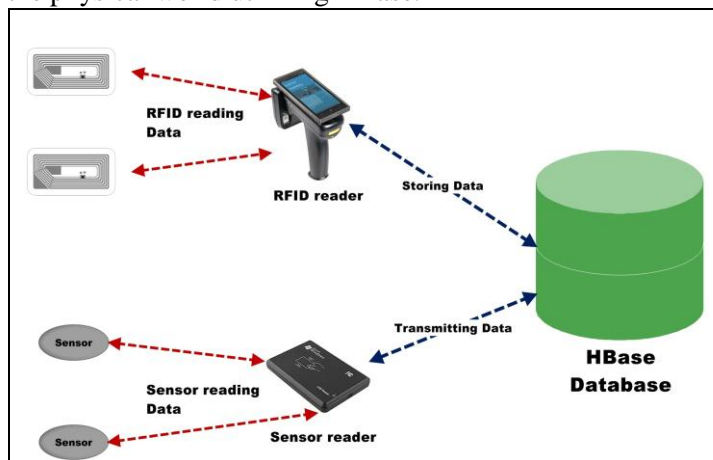

Fig. 3. RFID Sensor integrated into single system (HBase).

3.2. RFID/Sensor integrated into single system (HBase)

Radio Frequency Identification is putting away and recovering information by means of electromagnetic transmission utilizing a Radio Frequency. Since sensors can provide various sensing capabilities to RFID tags. A sensor in wireless sensor network is sense the data and forwards the particular data to an RFID reader for reading. RFID Reader consists of reading data and writing data this can be transmitted to the database for efficiently accessing data. Storing capacity in HBase is 2TB. The figure 3 shows how RFID/Sensor integrated into single system (HBase).

3.3. HBase Database

HBASE is a kind of NoSQL database that stores information in a segment arranged, conveyed, exceptionally solid and on a level plane versatile organization. The strategy separated from the Apache Hadoop with Java programming language from the Apache Software Foundation. Since HBase gives a profoundly accessible, adaptable, steady, and

ease arrangement. HBase keeps running over the HDFS and appropriate for quicker compose and read activities on enormous datasets with high throughput and low input/output latency. HBase uses master-slave architecture. HBase master keeps the Meta information about all the slave region servers and there are two types of files for storage, write-ahead log and other files to store actual storage of data. The files are handled by the region servers.

3.4. HBase Master/Slave Architecture

3.4.1. HBase Master

HBase Master is answerable for assigning tasks to area servers and executes administrative operations. Since master gets the request and forwards it to the corresponding region server. ROOT region is allocated primarily from which all assigned META regions can be found. Master tracks the running status of every area server, for example when it finds a district server bombs those locales moves to bombing area servers HBase Master likewise handles the table administration errands, for example, turning on/off the table, modifying the table structure (include or expel segment family), and so on. The HBase Master/Slave architecture is shown in the figure 4.

3.4.2. Region Server

Region Server is responsible for handling master requests. It interconnects with the HBase Master to receive a list of areas to tell and inform the master that it is alive.

3.4.3. Column oriented storage for HBase Data Model

HBase is a multi-dimensional, hashed map table, sparse, long-term storage. All of the table's data are strings where the type of data is not used. Data is stored in HBase tables with row keys, family of columns, qualifier of columns, time stamp and cell. This is a terminology overlap with MYSQL and Mongo DB, but these two databases are not helpful analogy. The row keys, maps to a list of column families and list of time stamps, each of which map to a value. Column family holds column qualifier. The conceptions of HBase data model is detailed in below:

- HBase Table: Table that is made of rows and columns.
- Column be in the right place to a family of columns.
- Row is uniquely identified by its key.
- Cell: coming together of a row and a column
- Row Key: Data in the table sorted in row key's byte order and the keys are similar to primary key.
- Timestamp: Each operation of the information corresponds to a timeline. A storage unit is called a cell which is determined by the row and rows. Each cell contains several versions of the same information sources indexed by timestamp and chronologically listed.
- Column Family: Every segment family relates to a capacity table in the level bearing. It comprises of at least one segment family and each column family contains any number of column qualifiers. Column Family supports dynamic development, all columns are stored in binary format without a predefined type of column, and the user needs to perform a transformation of their own type.
- Cell: Cell is a unit, made out of by lines, segments and timestamps. There are no information types in the cell and every one of the information put away in the byte code structure.

3.5. HBase create table Syntax for a single column

The example for HBase data model is shown in figure 5 and syntax to create table for single column is shown below:

Create '<table name>', '<column family>'
HBase create table Syntax for Multiple Column:

Create '<table name>', '<column family 1>', '<column family 2>' '<column family n>'.

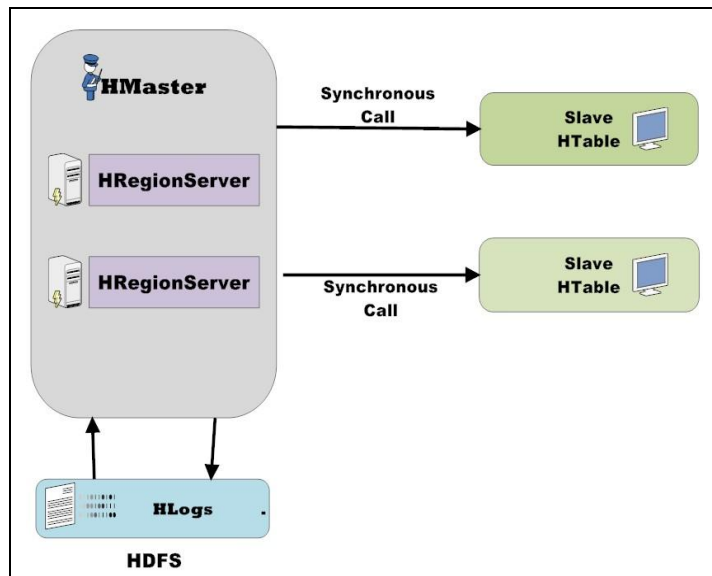

Fig. 4. HBase Master/Slave architecture.

4. Implementation

The Complete proposed system is designed to scale IoT generated data, such as RFID/Sensors reporting, storing and sensing data information continuously to the HBase. Because the system is designed to be scalable, efficient and perform very faster manner than other databases like Mongo DB and MySQL. In order to measure the time, when storing large number of data set or records in HBase, the following configurations need to implement the HBase:

It need 64-bit platform with Dual core CPU 2.2 GHz, 4GB memory, Ubuntu 8.10 Linux system and 80GB storage. To implement the Cloud system, the software development environments and tools are JDK 1.6, Hadoop-0.20.2 and HBase-0.20.5. During the Hadoop installation, one node runs the HBase master and the other nodes run as region servers (the server's actually storing and serving data).

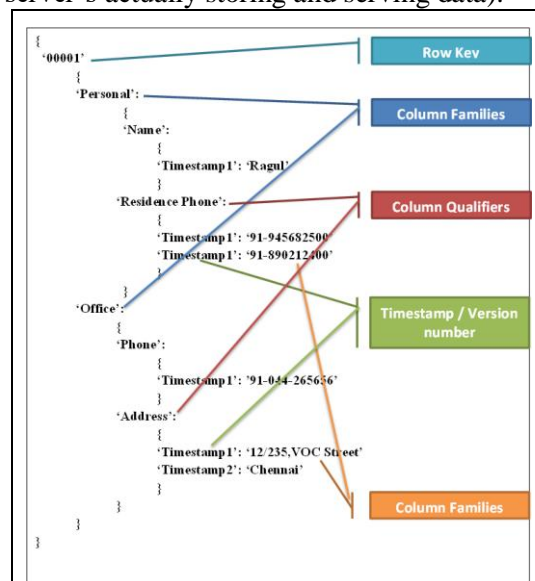

Fig. 5. HBase data model.

4.1. HBase Data Model

```

Row Key {
  Column Family 1 {
    Column i
      t1 value 1
      t2 value 2
      t3 value 3
    Column j
      t4 value 4
      t5 value 5
      t6 value 6
  }
  Column Family 2 {
    Column x
      t7 value 7
      t8 value 8
      t9 value 9
    Column y
      t10 value 10
      t11 value 11
  }
} {Row Key, Column Family, Time Stamp, Value}
    
```

4.2. HBase Performance Test

It tests the performance of Column family and Query Speed. In which three tests are performed. They are Column Family Test, Random Read Test and Query/Data speed Test.

Table.1.Column family test.

	Master									
Experiment	1 Region Server					10 Region Server				
Column Family	1	10	100	500	1000	1	10	100	500	1000
Write/sec	15	159	330	427	500	3	35	160	384	456
Read/sec	10	93	142	128	123	112	129	121	128	156

Table.2.Random read test.

	Master									
Experiment	1 Region Server					10 Region Server				
Rows	1000	10000	100000	1000000	10000000	1000	10000	100000	1000000	10000000
Reads/sec	140	103	58	25	15	150	108	42	15	8

Table.3.Query/ data speed test.

	Master									
Experiment	1 Region Server					10 Region Server				
Rows	1000	10000	100000	1000000	10000000	1000	10000	100000	1000000	10000000
Query efficiency/sec	1.40	10.3	58.9	90.78	140.67	0.495	3.145	22.644	42.344	49.678

4.2.1. Column Family Test

The motivation behind this column family test is to investigate the expansion of the relationship estimating the presentation of different segment families. In the experiment, for each column family, 1000 bytes of data are assigned and any of the columns are read. The result is listed in the following Table 1. Table 1 outcomes demonstrate that HBase bolsters a huge group of memory segments where writing pace is altogether quicker than reading speed. The speed of information on just one server is moderate, while it gets faster in a cloud situation. \Bw\ut the composing and perusing pace have dropped when the quantity of section families more than 100. The reason is as underneath. Every column family in HBase is put away independently. Consequently, composing and perusing rate turns out to be slower with the expansion of the quantity of section families.

```
Create new table: Table as "Test" Column family as "cf":
HBase (main): 006 : 0 > create 'test', 'cf'
0 row(s) in 3.3340 seconds
=> HBase : :Table - test

Inserting Value in HBase Table:
HBase (main) : 008 : 0 > put 'test', 'row1', 'cf:a', 'val-ue1'
0 row(s) in 1.3280 seconds
HBase (main) : 009 : 0 > put 'test', 'row2', 'cf:b',
'value2'
0 row(s) in 0.0340 seconds
```

4.2.2. Random Read Test

The aim of this experiment is under the huge volume of table to evaluate the read operation more effectively. The following Table 2 shows the 5000 rows were read effectively from the table. The findings in Table 2 indicate that when just single region server is used, HBase read velocity slows down as the amount of rows rises, and in cluster mode comparatively better. This indicates that, in a very huge quantity of data per table, HBase doesn't really favor the extension. The two major reasons for this problem are as follows, if the table is very big, an arbitrary reading will have to access the disk instead of memory and second, as their size rises, the processing of data structure will become expensive.

4.2.3. Random Read Test

The aim of this experiment is under the huge volume of table to evaluate the read operation more effectively. The following Table 2 shows the 5000 rows were read effectively from the table. The findings in Table 2 indicate that when just single region server is used, HBase read velocity slows down as the amount of rows rises, and in cluster mode comparatively better. This indicates that, in a very huge quantity of data per table, HBase doesn't really favor the extension. The two major reasons for this problem are as follows, if the table is very big, an arbitrary reading will have to access the disk instead of memory and second, as their size rises, the processing of data structure will become expensive.

4.2.4. Query/Data speed test

The motivation behind this experiment is to demonstrate the query effectiveness on various information tables' quantities. A value is queried in 1000, 10000, 50000 and 100000 data rows respectively in the experiment. The outcome of the experiments is showed in Table 3. The findings in Table 3 indicate that the database query speed in the various cluster environment is considerably enhanced. Structure of HBase tables are loosely coupled and HBase has detachable framework. There are just the connections between them among basic and direct key-value pairs. There are no perplexing

connections between tables or relationship exercises. Thusly, to find the objective data, the attribute query must navigate the table's whole content.

5. Evaluation

A. Comparison of HBASE with MYSQL

HBase allocates an alternative for relational database as it's much faster as compared to MySQL. It stores information in a raw byte format and hence takes much less time in reading and writing data and a comparison is done, i.e. HBase with MySQL. A series of tests are performed on similar kind of data to compare the performance gain.

1) Random Write Operation

The table below displays the comparison of random write operations performed for both MySQL and HBase. The results are checked by taking different number of records each time. The table conveys a greater difference in the performance of the databases. The Figure 6 shows that the performance of HBase compared with MySQL. The ratio of time between HBase and MySQL is 1:9 for write operation.

Table.4.hbase random write vs. Mysql random write.

No. of Records	HBase Time in seconds	MySQL Time in seconds
90	0.127	0.39
900	2.106	3.255
9000	14.00025	32.14
90000	144.9815	319.637
900000	1745.614	3184.861

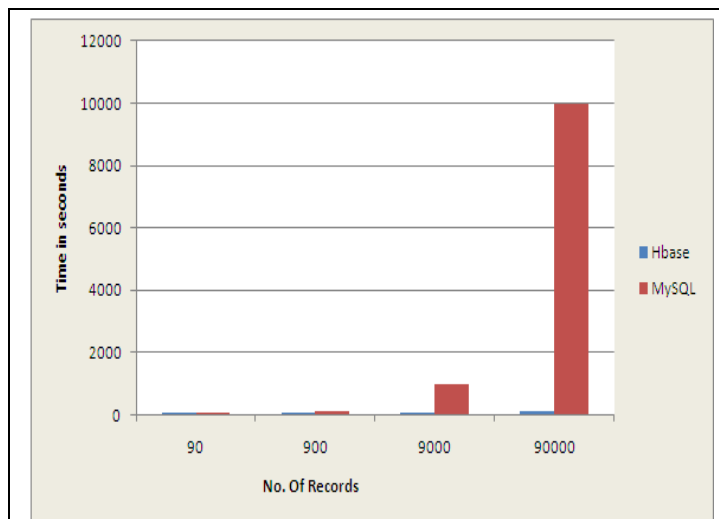

Fig.6 .Comparison of HBase with MySQL for Write Operation.

2) Random Read Operation

HBase outperforms Random read operation compare with MySQL. Here HBase take much less time as compared to MySQL to reading the same number of records. Table 5 shows the results for both HBase and MySQL databases.

Table.5.Hbase random read vs. Mysql random read

No. of Records	HBase Time in seconds	MySQL Time in seconds
----------------	-----------------------	-----------------------

90	0.127	0.39
900	2.106	3.255
9000	14.00025	32.14
90000	144.9815	319.637
900000	1745.614	3184.861

Figure.7. shows that the performance of HBase compared with MySQL with respect to write operation. The ratio of time between HBase and MySQL is 1:2 for write operation.

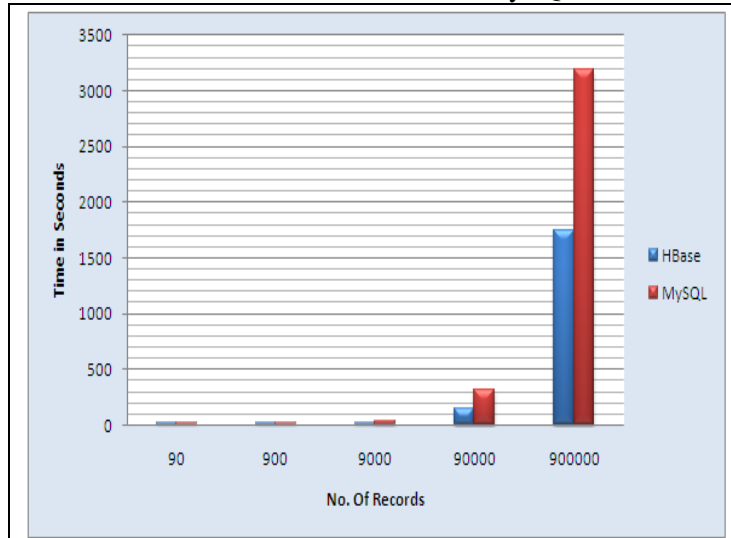

Fig.7 .Comparison of HBase with MySQL for Read Operation.

B. Comparison of HBASE with Mongo DB

Next, compared the write and read performance of HBase and Mongo DB. At first it performs read operation and then performs a write operation. In this experiment, multiple records that were stored in both HBase and Mongo DB.

1) Read Test

In Reading test, HBase peruses 37.2 million records. Each record comprises of 111 fields. Also, it is a similar kind of information records was put away. Mongo DB the time is shifted. For this record size, HBase can peruse at a pace of 9.3 million records for each moment and from Mongo DB at a pace of 2.7 million records for every moment. The figure 8 shows the comparison of HBase with MongoDB for read operation. The Table 6 shows the results for both HBase and MongoDB databases.

2) Write Test

For compose activities, the records had just comprised of field, this implies the records being composed were around multiple times littler than the records were perused. When considering HBase compose execution, 19 million records in 15 seconds (74.5 million records/minute), though Mongo DB takes 360 seconds for 19 million records (3.2 million records/minute). In rundown, there is a 3:1 proportion among HBase and Mongo DB in perusing execution for huge records and an essentially bigger 24:1 distinction recorded as a hard copy execution for few records. The figure 9 shows the performance analysis for HBase and Mongo DB. Table 7 shows the results for both HBase and MongoDB databases.

TABLE.6. HBASE RANDOM WRITE VS. MONGO DB RANDOM WRITE

No. Of Records	HBase (Time in Seconds)	Mongo DB (Time in Seconds)
9	1.395	4.185

90	13.5	40.5
900	135	405.67
9000	1350	4050

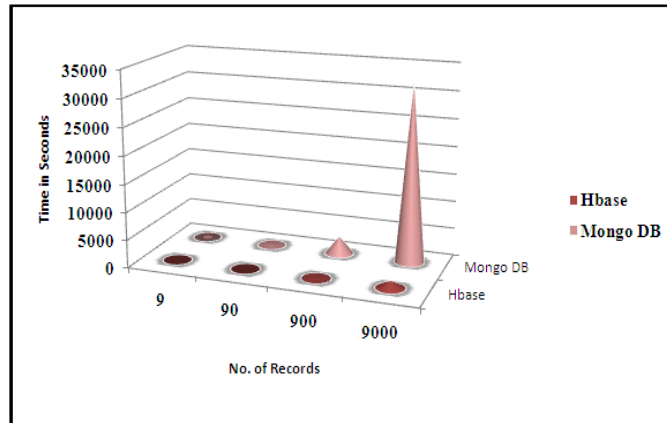

Fig.9.Comparison of HBase with Mongo DB for Write Operation.

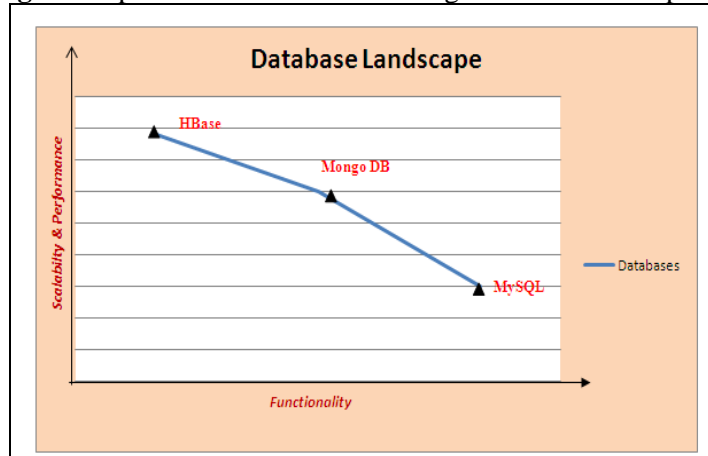

Fig.10.Comparison analysis for overall Databases.

C) Comparison analysis for overall Databases

The comparison analysis has taken for overall databases such as HBase, MongoDB and MySQL. The difference between HBase, MySQL and MongoDB is size of storage space in the database is differs. HBase is a NoSQL database that is stored column oriented form, hence Mongo DB also NoSQL database that is stored in tabular form and in HBase storage value size is 2TB and MongoDB size is only 16MB and MySQL is SQL database that is stored in tabular form but in HBase it's not necessary to specify the data type for row and column value like in MySQL is not working without mentioned any data type. The below graph compares the functionality of databases and shows that HBase has high scalability and performance evaluation by comparing other two databases.

Table.7. HBase random read vs. MongoDB random read.

No. Of Records	HBase (Time in Seconds)	Mongo DB (Time in Seconds)
9	1.395	4.185
90	13.5	40.5

900	135	405.67
9000	1350	4050

6. CONCLUSION

Smart devices and Ubiquitous computing ruling the today's internet world. All the smart devices must utilize different RFID and sensor systems to monitor the devices and connect with internet which will be the future IoT. Many scientists have been researching the integration of sensor and RFID techniques in multiple study problems. The attempts being made in this article is to incorporate RFID and Sensor techniques in HBase on the same IoT platform. Unlike standard NoSQL databases that only provide architecture-level IoT platforms, this article suggested a RFID / sensor data repository execution model based on HBase and large data processing is stored in the cloud-based setting. In terms of storage, even data distribution and query response time, the suggested RFID / sensor information repository has been empirically demonstrated. A comparison of HBase with some other column-oriented databases will be introduced in the future to improve data storage repository.

Spalling

ABSTRACT

Fire accidents are inevitable and it is one of the significant hazards, which causes loss of life and valuables. The present investigation focused to study the influence of fibers on shear strength of concrete exposed to elevated temperature as per ISO 834. The fibers used in the study were Basalt, Carbon, Glass, Polypropylene and Poly vinyl alcohol. M20, M30, M40 and M50 grades of concrete were used for the investigation. The results revealed that the shear strength is declined with increase in temperature. The shear strength is enhanced by the addition of fiber in the reinforced concrete beams exposed to elevated temperature. Carbon fiber reinforced concrete specimens exhibited better residual shear strength than the other specimens. Addition of carbon fiber and basalt fiber in concrete reduced the micro cracks in the specimens exposed to elevated temperature. Addition of polypropylene fiber and poly vinyl alcohol fiber reduced the spalling but the crack propagation was not prevented in the specimens exposed to high temperatures.

1. INTRODUCTION

Fiber Reinforced Concrete (FRC) is known for many property enhancements in conventional concrete. There are numerous studies carried out during last three decades to overcome the weak tensile behavior of concrete. The performance of concrete is always associated with its compressive strength and tensile strength. These two properties are much important that decides the characteristics of concrete. The fibers added in concrete helps to reduce the brittleness of the concrete by bridging the micro cracks and thus prevented the macro crack

development [1]. Only limited studies have been carried out on the effects of elevated temperature on the shear strength of FRC. Majority of the investigations focused on the effect of steel fibers and PolyPropylene Fiber (PPF) on the shear strength of the concrete. Considering FRC in terms of fire resistance, some tests have been conducted to identify the effect of fibers in resisting the fire related damages that occurs in concrete structures [1, 2]. Mainly, these are emphasized on the effect of fibers on the basis of its shape, type and the percentage of addition (quantity) on the strength parameters of concrete. Commonly the experiments are carried out in

*Corresponding Author E-mail: davids1612@gmail.com (N. Anand)

terms of compressive strength, tensile strength and modulus of elasticity [1–5]. Widely used fibers in the concrete industry are synthetic fibers such as PPF and Poly Vinyl Alcohol Fiber (PVAF), Steel Fibers (SF), and hybrid of SF and PPF. There are also a few examinations, which tested concrete with Carbon Fibers (CF), and Glass Fibers (GF) [4, 5].

Kurup and Senthil-Kumar [6] found that addition of PVC fibers improved the ductility behavior of concrete and reduced the brittle failure of concrete. Shear strength values were reduced in the case of fiber reinforced concrete with respect to the addition of PVC fibers and silica fibers (0.6 to 1%) [6]. Bae et al. [7] concluded that, an increase in shear strength according to inclusion of steel fiber was more effective than the four times volume fraction of shear reinforcement. Based on experimental results of the study conducted by Abdi Moghadam and Izadifard [8] it is found that although the inclusion of steel fibers decreased the compressive strength, it has improved the shear strength of plain concrete at 28 days of curing. Smith et al. [9] experimentally investigated the shear strength of fire affected (622°C) beam specimens. The rate of heating was 10°C/min. It was found that 30% reduction in shear strength occurred. Cai et al. [10] studied the residual shear strength of concrete beam specimens after exposure to ISO 834 time temperature curve and the reduction in shear strength was found. For the exposure time of 30 min., 60 min. and 90 min the shear strength reductions were 15, 23 and 26%, respectively. Yusuf [11] examined the residual shear strength of concrete push off specimens after exposure to 200°C, 350°C and 500°C with a rate of 17°C/h. heating. The residual strengths after the specimens exposure to 200°C, 350°C and 500°C, were 26%, 41% and 66%, respectively. Concrete with PP fibers showed the negative performance on improving the mechanical properties beyond the critical temperature (more than 500°C). It was due to the loss of bond between the fiber and cement matrix. It may be due to the development extra pores during melting of PPF [12–14]. Information are limited on the effect of fibers on shear strength of concrete exposed to elevated temperature.

The shear strength is a significant property, which enables concrete to withstand against the fatigue forces. It is considerably less than the compressive strength, because the micro cracks developed in concrete can spread and widen under bending loads. When exposed to fire, bending strength of concrete is reduced due to the spalling that occurs within concrete elements [15–17].

Information on the residual shear strength of FRC with CF, Basalt Fiber (BF), GF, PPF and PVAF exposed to standard fire curve (ISO 834) was found to be missing in the literature. Effect of elevated temperature on FRC with different strength grades are to be evaluated. Hence, it is necessary to understand the influence of different types of fibers on the strength and surface defects of

concrete when exposed to elevated temperature. An attempt has been made to study the key factors such as type of fibers, grade of concrete and intensity of temperature, which affect the residual shear properties of concrete.

This paper investigates the shear response of FRC exposed to elevated temperature. The fibers used in the study are BF, CF, GF, PPF and PVAF. The study was conducted in M20, M30, M40 and M50 grades of concrete. Residual shear capacity of different grades of concrete with different fibers are presented in this work.

The main objective of the investigation is to examine the influence of fibers on the shear strength of concrete after exposure to elevated temperature.

2. EXPERIMENTAL INVESTIGATION

2. 1. Materials

The ordinary Portland cement of grade 53 conforming to IS: 12269–2013 and Manufactured sand (M-sand) as fine aggregate (Zone II) as per IS: 383:2016 were used. Crushed granite stones of size 20mm conforming to IS 383:2016 were used as coarse aggregate. The quality of water was found to satisfy the requirements of IS 456:2000. Considering the properties of materials, the mix proportion of concrete was designed as per IS 10262:2019. A water reducing agent Master Glenium SKY 8233 was used to control the workability (slump cone test) of all concrete mixtures. The water reducing agent maintained the workability of the mix in between 75 and 100mm even after the addition of fibers into the mix without affecting the water cement ratio. Fe 500 steel bars were used as reinforcement. Table 1 shows the details of fibers.

2. 2. Preparation of Specimens and Test Procedure

Singly reinforced FRC beams were cast and used for testing the shear behavior after exposure to elevated temperature. 700 x 150 x 150mm size beams were used for the investigation considering the limitation of the furnace size. Two numbers of 6mm diameter bars were used at top and bottom of the specimens. In order to ensure shear failure, two legged 6mm diameter stirrups are provided at supports and loading points only to hold the main bars (Figure 1). With respect to the proposed

Figure 1. Details of RC beam

beam size molds were made with cast iron. The two-point loading arrangement was adopted from IS 516:1959.

After 24 hours of casting, the sides of the formwork were removed and the specimens were cured in water for 28 days. After curing, specimens were dried and heated following stranded fire curve.

A computer controlled electrical furnace with inner dimensions of 700 × 400 × 400 mm having the capacity power of 100kW was used to heat the specimens (Figure 2). The maximum operating temperature of the furnace is 1200°C, with a capability to set the standard fire temperature curve (Equation (1)). Type K thermocouples connected to a microprocessor based data acquisition unit were used to monitor the temperature inside the furnace.

$$T - T_0 = 345 \log_{10}(8t + 1) \quad (1)$$

Concrete specimens were exposed to heating durations of 30 min (821°C), 60 min (925°C) and 90 min (986°C) as per standard fire curve (Figure 3) following ISO 834. Heated specimens were cooled in ambient condition before the test. The furnace temperature of the heated specimens and its surface cooling rate are shown in Figure 3. The investigation was carried out for different grades of concrete such as M20, M30, M40 and M50. After cooling in air, the shear resistance of Reinforced Concrete (RC) beams were tested using a computerized Universal Testing Machine (UTM) of capacity 1000 kN. Two-point load was applied with appropriate test setup to ensure constant shear in the specimens. The loading gauge was connected with the digital testing machine that records the failure load of the specimens. After curing, cube specimens were exposed to 90 minutes of elevated temperature (986°C) to observe the surface defects. Figure 4 shows the methodology adopted.

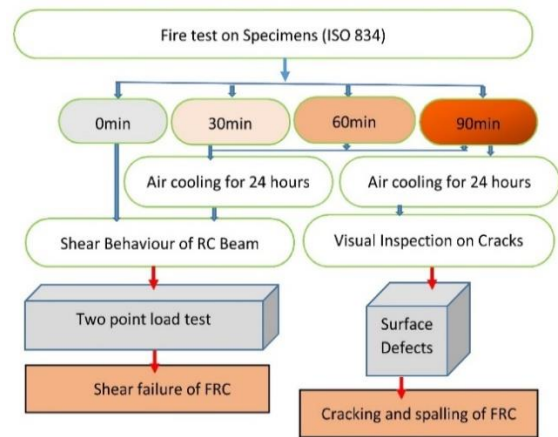

Figure 4. Methodology

3. RESULTS AND DISCUSSION

3.1. Shear Strength During loading, shear failure was observed in the beam specimens and it is confirmed by the diagonal cracks developed near the support (Figure 5). The ultimate load was delayed according to the type of fibers added in the concrete specimens. For the RC specimens exposed to elevated temperature, the shear resistance decreased with the increase in the duration of elevated temperature.

Figure 5. Shear failure of specimen and inset view of crack

3. 1. 1. Effect of Fiber Type on Unheated FRC

Tables 2 to 5 summarized data for the shear failure load of different FRC specimens. It is evident from the results, that all the FRC specimens exhibited more shear capacity than the control concrete (CC). The increment of shear resistance of FRC with respect to CC were found to vary according to the fibers added in the concrete. In the case M20 grade unheated CC specimens (Table 2), carbon FRC (CFRC) exhibited 1.7 times the shear resistance of CC. This was followed by Basalt FRC (BFRC) (1.6 times) and Glass Fiber Reinforced Concrete (GFRC) (1.5 times). The significant increase in the shear strength may be due to the high tensile load carrying capacity (Table 1) of CF, BF and GF [18]. Poly Vinyl Alcohol FRC (PVAFRC) and Polypropylene FRC (PPFRC) specimens exhibited a marginal increase (1.2 times) in shear strength with respect to CC. All FRC specimens exhibited more shear resistance than the CC specimens for M20, M30, M40 and M50 grades after exposure to elevated temperature for 30, 60 and 90 minutes of exposure duration.

Figure 6 depicts the increment in shear resistance of unheated M20, M30, M40 and M50 grade specimens with respect to unheated CC. It is evident that the increment of shear resistance is depended on the elastic modulus and tensile strength of fibers added in the concrete. The results proved that fibers with high tensile strength (CF) has the highest ratio of shear resistance in an unheated condition (1.7 for M20 grade CFRC, 1.5 for M30 grade CFRC, 1.7 for M40 grade CFRC and 1.6 for M50 grade CFRC). This was followed by BFRC, GFRC, PVAFRC and PPFRC specimens that have a lower shear strength (Tables 2-5).

3. 1. 2. Contribution of Fibers in Concrete Exposure to High Temperatures

Figures 7 - 10 show the comparison of the shear resistance of M20 (Figure 7), M30 (Figure 8), M40 (Figure 9) and M50 (Figure 10) grade heated FRC specimens with respect to the heated M20 grade CC, M30 grade CC, M40 grade CC and M50 grade CC specimens. This was calculated by taking the ratio of shear resistance of any specimen with the shear resistance of control concrete (CC) of a same grade exposed to same elevated temperature. It can be seen from the figures that, M20 grade CFRC, M30 grade CFRC, M40 grade CFRC and M50 grade CFRC exhibited the maximum shear resistance when exposed to elevated temperature for durations of 30, 60 and 90 minutes. These figures clearly indicate the contribution of fibers in improving the shear resistance of FRC exposed to higher temperature. The fibers in the heated M20 grade CFRC specimens exhibited almost similar contribution in the shear resistance (1.8 times) even after exposed to 30, 60 and 90 minutes. Similar phenomenon was visible on shear resistance of M30 grade CFRC, M40 grade CFRC and M50 grade CFRC specimens.

Figure 6. Ratio of shear resistance for unheated specimens

The shear resistance of M20 grade BFRC specimens were found to be 1.5 times that of the M20 grade CC specimens at elevated temperature conditions (30, 60 and 90 minutes). In addition, M30 grade BFRC (1.5 times), M40 grade BFRC (1.6 times) and M50 grade BFRC (1.6 times) exhibited similar behavior in the case of temperature exposed conditions. There was a sudden drop in the shear resistance of M20 grade GFRC specimens (1.4 times to 1.2 times) when exposed to 90 minutes of elevated temperature. M30 grade GFRC, M40 grade GFRC and M50 grade GFRC also exhibited a similar pattern. It may be due to the loss in tensile

strength of glass fiber when exposed to elevated temperature [19]. With prolonged heat exposure, the shear resistance of the specimens declined but it can be strengthened by increasing the tensile strength of concrete [10].

In the case of M20 grade PPFRC and M20 grade PVAFRC specimens, a sudden drop (1.2 times to 1.06 times) was observed on the shear resistance of concrete, when exposed to 60 and 90 minutes. In the case of PPFRC and PVAFRC, the similar pattern is observed for other grades (M30, M40 and M50) of concrete. It may be because of the low melting point of these fibers which causes melting of fibers inside the specimens when exposed to elevated temperatures. This reduced the tensile strength of fibers in heated specimen compared to CC. The melting of fibers leads to the creation of pore holes in concrete specimens, which helps to reduce the crack propagation [20, 21]. Hence it shows better shear resistance capacity (1.1-1.2 times) than CC.

Figure 7. Shear resistance of M20 heated FRC specimens

Figure 8. Shear resistance of M30 heated FRC specimens

Figure 9. Shear resistance of M40 heated FRC specimens

Figure 10. Shear resistance of M50 heated FRC Specimens

3. 2. Thermal Crack Formation

Figure 11 (11A, 11B, 11C, 11D, 11E, 11F) shows the surface view of M20 grade specimens heated up to 90 minutes. It is evident from the figures that the M20 grade CC had more surface pitting than the BFRC, CFRC, GFRC, PPFRC and PVAFRC specimens. For PPFRC and PVAFRC specimens, only surface pitting was observed. This is because of reduction in pore pressure through pore channel created when these specimens exposed to elevated temperature [20] GFRC, BFRC and CFRC specimens had less thermal cracks than CC. It may be due to the bridging effect of high melting point fibers (GF, BF and CF) [22]. The GFRC have small amount of progressive cracks. This is because of the reduction in the tensile capacity of GF, when it is exposed to elevated temperature [19]. Hence reduction in bridging effect between cement matrixes occurs.

Figure 11. Surface view of specimens: A. M20 CC, B. M20 PPFRC, C. M20 PVAFRC, D. M20 GFRC, E. M20 BFRC, F. M20 CFRC, G. M30 CC, H. M40 CC and I. M50 CC

Also Figure 11 (11A, 11G, 11H, 11I) shows the surface view of the M20 grade CC, M30 grade CC, M40 grade CC and M50 grade CC specimens after being exposed to 90 minutes of heat exposure. From the visual inspection, it is identified that M50 grade CC has the maximum surface damage when compared to M20 grade CC specimens. This may be due to the high density of concrete (M50 grade CC) with less porosity [2]. When the specimens were exposed to elevated temperature, the pore pressure developed within the concrete is high in higher-grade concrete and this induced more surface cracks.

4. CONCLUSIONS

FRC specimens were exposed to elevated temperature up to 90 minutes' duration of heating following the standard fire curve. Shear resistance of FRCs were analyzed before and after heating. The higher grade concrete (M50) is found to retain high shear strength. Addition of fibers improved the shear strength of concrete. The effect of fibers on concrete in terms of shear strength and crack control after being exposed to elevated temperature are concluded below:

- The concrete specimens with CF show better residual shear strength in all grades and at different temperature levels. For 90 minutes of heat exposure, CFRC retained 116 and 91% shear strength of the unheated CC specimen for M20 grade and M50 grade, respectively.
- Concrete specimen with BF (99 - 86%) and GF (80 - 61%) also exhibited high shear strength after exposure to 90 minutes of elevated temperature but the shear strength was found to be lower than that of concrete specimens with CF.
- The residual shear strength of the PPFRC and PVAFRC specimens after exposure to 30 minutes, were found to be 115% (M20) - 108% (M50) and 116% (M20) - 109% (M50), respectively. From 60 minutes of heat exposure onwards, residual shear strength was found to be decreasing. In addition, at 90 minutes of heat exposure, PPFRC and PVAFRC specimens exhibited marginal increment in shear strength than control concrete specimen. It is proved that fibers improve the shear resistance of concrete exposed to elevated temperature. Also addition of fibers prevented the spalling of concrete specimens.
- The concrete specimens with CF and BF were found to have minimum micro cracks even after exposure to elevated temperature. Addition of PPF and PVAF reduced the spalling but the crack propagation could not be prevented at high temperatures. The specimens with GF had more cracks and more surface damage after the exposure. Concrete with higher strength grade (M50) had high rate of crack propagation.

The results of the research are applicable for RC beams exposed to standard fire following ISO 834 fire curve. In case of external fire curve, the behavior of fiber reinforced concrete may change. In addition, there is a scope to compare the performance of different FRC with the corresponding optimum volume fraction of fibers.

5. ACKNOWLEDGEMENT

The authors wish to acknowledge the Science and Engineering Research Board, Department of Science and Technology of the Indian Government for the financial support (YSS/2015/001196) provided for carrying out this research.

ABSTRACT

Concrete is a building material having good fire resistance and the resistance depend on many factors including the properties of its constituent materials. Fiber Reinforced Concrete (FRC) apart from improving mechanical properties has better fire resistance than conventional concrete. Bond strength of concrete is one of the important properties to be considered by structural engineers while designing reinforced concrete cements. In this research, an experimental investigation has been carried out to determine the effect of fibers on the bond strength of different grades (M20, M30, M40 and M50) of concrete subjected to elevated temperature. Different types of fibers such as Aramid, Basalt, Carbon, Glass and Polypropylene were used in the concrete with a volume proportion of 0.25% to determine the bond strength by pull-out test. Prior to the pull-out test, the specimens were kept in a furnace and subjected to elevated temperatures following standard fire curve as per ISO 834. Based on the test results of the investigations, type of fiber, grade of concrete and duration of heating were found to be the key parameters that affect the bond strength of concrete. The contribution of carbon fiber in enhancing the bond strength was found to be more significant compared to other fibers. An empirical relationship has been developed to predict the bond strength of FRC at a slip of 0.25 mm. This empirical relationship is validated with experimental results.

Bond strength; elevated temperature; fiber reinforced concrete; standard fire curve; Pull-out test

1. Introduction

The nature of failure of concrete structural elements exposed to fire shows a discrepancy due to factors such as rate of heating and magnitude of temperature. Failure of concrete may be due to loss of compressive, tensile, flexural, and bond strengths that results in spalling of concrete [1]. Significant strength loss was examined for concrete after the exposure to 600 °C [2]. There were some changes that had occurred in the pore structure due to cracking, spalling, destruction of the bond between cement paste and aggregate when the concrete was exposed to elevated heat [3,4]. In the case of

Reinforced Cement Concrete (RCC), bond strength between reinforcing steel and concrete is reduced due to fire exposure.

There is a growing interest in FRC because of its properties of the reinforcing fibers which improves the properties like fire resistance, stiffness and bond strength of concrete. Severe heat exposure can adversely affect the mechanical properties of concrete. It also leads to thermal incompatibility between concrete and steel. The high vapour pressure developed due to the inner moisture of concrete subjected to high temperature is not released by micro channels, which results in cracking and loss of strength of concrete [5].

Failure of reinforced concrete members exposed to fire may occur mainly due to the reduction in bond strength between the steel and concrete. Bond failure in concrete is due to the rapid reduction in the tensile strength of concrete as the temperature gradient rises within the concrete [6]. Reduction in bond strength depends on the duration of heating and the level of temperature to which the concrete is exposed. With the increase in temperature, bond stress decreases and the slip value increases [7]. Compressive strength of concrete, diameter of bar, concrete cover and embedded length are some of the factors that affect the bond strength of concrete. Application of fiber in concrete is one of the means to enhance the fire resistance of concrete. Recent researches indicate that the application of some types of fibers in concrete can improve the residual mechanical properties of concrete after exposure to elevated temperature [8]. When the pore pressure develops during heating, it exceeds the tensile strength of concrete and explosive spalling occurs. In this explosive spalling mechanism, thermal stress takes part in the development of strain energy [9].

Bond strength is the resistance to slipping of the steel bar, or separation of concrete around the bar which is embedded in concrete. This property is of a great significance in structural design of concrete members [10]. Moreover, the transfer of stress between concrete and steel has a great influence in controlling the width of cracks [11,12]. Effective bond creates the composite action between steel and concrete. Better performance of reinforced concrete members can be ensured only if there is an adequate bond between concrete and steel [10]. The aim of this study is to identify the suitability of fibers (Aramid, Basalt, Carbon, Glass and Polypropylene) for enhancing the bond strength of concrete exposed to elevated temperatures.

Many research works carried out on mechanical properties of FRC subjected to elevated temperature are available in literature [2,8,13–20]. Although bond strength is one of the major characteristics in reinforced concrete structures, only very limited information is available concerning the residual bond strength of different fiber reinforced concretes after exposed to high temperature. For the present study, the specimens were heated as per standard fire curve following ISO 834.

Concrete and steel maintaining a good bond by composite action so that it is used as a construction material known as reinforced concrete. It was reported [6,7,11] that there was a considerable loss in bond strength as the temperature was increased. The findings of these studies showed that the residual bond strength varies between 20% and 60% based on key factors such as the properties of concrete and rebar, diameter of rebar, embedment length of rebar, regime of heating and cooling etc.

The different studies showed a significant effect of surface characteristics of rebar, confinement of concrete, basic properties of concrete (w/c ratio, cement and aggregate

type, additives), maturity, relative humidity, and testing conditions (heating and cooling duration and rate, and testing while hot or cold) on concrete–steel bond behavior under a wide range of high temperature conditions. Earlier researches [6,7,11] explored the applications of steel fibers, polypropylene fibers or the combination of this two fibers to enhance the performance of concrete.

The present study investigates the contribution of synthetic fibers (CF,BF,AF,GF,PPF) on improving the bond strength between matured concrete and reinforcing steel at high temperatures as per standard fire. The present research explores the application of fiber with low and high melting point. The lack of information or knowledge in this area needs to be addressed so that engineers can choose the right fiber for the application. Hence the type of fiber, grade of concrete and duration of heating were considered as key factor. An empirical relationship has been developed to assess the residual bond strength of concrete with different types of fibers.

2. Materials & methods

2.1. Materials

Plain and FRC concrete were used in the study. Five types of fibers namely Aramid, Basalt, Carbon, Glass and Polypropylene fibers (Figure 1) were used to develop FRC with constant dosage 0.25% of concrete volume. The properties of constituent materials and details of mix proportion used for the investigation are given in Tables 1 and 2, respectively. Master Glenium SKY 8233 as a water reducing admixture (Super plasticizer) was used for maintaining the work ability (75 to 100 mm) during concreting. However the water cement ratio was carefully selected based on the strength point of view. So suitable optimum percentage of SP was used for maintaining the slump for developing M40 and M50 concrete. In the case of M20 and M30 the selected water cement ratio satisfied the slump.

Ribbed steel bars of 12 mm diameter and 400 mm long were used as reinforcement rod in 100 mm concrete cube specimens. Table 3 gives the properties of different fibers used for the investigation.

Aramid Fiber (AF) is in a nature of crystalline aromatic polyamides. They possess low density and high tensile strength to weight ratio. AF does not melt and it withstand against fire but starts carbonization at 427 °C. The maximum temperature suggested for continuous use for AF is 160 °C. They have very low thermal conductivity. Except

CF	12	1.77	1200	240	–1.2
GF	12	2.55	1120	77	5.4
PPF	12	0.90	160	50	130

for a few strong acids and alkalis, their chemical resistance is good and has a negative coefficient of thermal expansion [21].

Basalt Fibers (BF) are produced by melting and processing of basalt rocks. The basalt rocks are divided into small fine particles to produce their fibers [22]. Previous researches have shown that addition of BF in concrete improves the thermal and mechanical properties of concrete [23]. Some researchers have studied the effect of BF on the mechanical properties of concrete. Heat resistance of BF can be explained in terms of natural basalt rock characteristics [24]. More over BF are not reacted with air or water and are non-flammable [25].

Carbon Fiber (CF) is a combined form of graphitic and amorphous carbon. Its high tensile modulus is a property of its graphitic form. It has negative coefficient of thermal expansion [21]. Carbon Fiber (CF) forms a bridge inside the concrete and resists crack propagation during loading. It also controls the volume change in concrete, that occurs by quick change of temperature and large temperature gradient. Due to this, it mitigates the initiation and expansion of inner micro defects of concrete. It is understood from the literature that it maintains higher residual strength of concrete after exposure to high temperature [26]. Glass Fiber (GF) is a material consisting of numerous extremely fine fibers of glass. GF are often preferred as reinforcement in a concrete due to their better impact resistance, good fatigue life and resistance against corrosion in most common environments [27]. The principal advantages of glass fibers are low cost, high tensile strength, high chemical resistance and excellent insulating properties. The disadvantages are relatively low tensile modulus, high density, sensitivity to abrasion during handling and relatively low fatigue resistance [21] which have no true melting point but softens up to 1200 °C [28]. GF are useful thermal insulators because of their high ratio of surface area to weight. However, the increased surface area makes them much more susceptible to chemical attack [29].

Polypropylene belongs to the polyolefin family of chemicals. The Polypropylene Fibers (PPF) are hydrophobic, they do not absorb water, and are not corrosive [30]. Due to this, balling is prevented in concrete with PPF during mixing. The fibers act as crack arresters. The concrete with PPF controls the propagation of cracks by holding the cement matrix together or bridging the cracks [30]. PPF melt at 160 °C and vaporize due to their lower melting point, which results in formation of micro channels in the concrete. Thus, greater vapour tension in capillaries can be alleviated and released, which may be the reason for the absence of explosive spalling in concrete with PPF [26].

2.2. Test setup

The concrete cube specimens of size 100 mm cast were cast and kept in a curing tank for 28 days. Reinforcement of diameter 12 mm and length 400 mm was inserted into fresh concrete specimen for a length of 100 mm. After curing, the specimens were surface dried for 24 hours prior to test. Then the specimens were wrapped by ceramic fiber around steel reinforcement rod to prevent the steel rod projections above concrete from heat. To determine the bond strength of concrete after exposure to elevated temperatures, a computer controlled electrical furnace with inner dimensions of 700 × 400 × 400 mm and a power of 100kW was used. The maximum operating temperature of the furnace is 1200 °C, with a capability to follow the standard temperature curve, Equation 1. Type K thermocouples connected to an automatic data acquisition were used to monitor temperatures inside the furnace.

$$T - T_o = 345 \log 10(8t + 1) \quad (1)$$

Where: T - Furnace temperature at time t (degrees Celsius), T_o - Initial furnace temperature (degrees Celsius), t - Time (minutes).

Concrete specimens were exposed to heating durations of 30 min (821 °C), 60 min (925 °C), 90 min (986 °C) and 120 min (1029 °C) as per standard fire curve (Figure 2(a,b)). Heated specimens were cooled in ambient condition before the pull out test (Figure 2(c)). The investigation has been carried out for different grade of concrete such as M20, M30, M40 and M50.

2.2.1. Pull-out test

As per IS 2770:1967 Part 1, pull-out test was carried out using Universal Testing Machine (UTM) [31]. The specimen was placed in UTM in such a way that the bar could be pulled axially from the cube (Figure 3(a,b)). The pull-out loads against slip were found and processed to obtain the relationship between bond stress and free end slip. Based on the literature [32–34], the critical bond stress is taken as the stress corresponding to a slip of the rebar considered was 0.25 mm ($BS_{0.25}$) (Figure 3(c)). The obligatory slip value of 0.25 mm is always lower than the one obtained when reaching the ultimate bond stress of unheated specimens. It may be noted that the critical bond stress ($BS_{0.25}$) is more conservative and more secure than BS_{max} . In this study, load and slip of reinforcing bar were recorded at sufficient number of intervals throughout the test, up to a slip of 0.25 mm. The bond stress was calculated for each specimen by

Figure 2. (a) Time temperature curve. (b) Specimens inside the furnace. (c) Specimens after exposed to elevated temperature.

dividing the applied load at the slip specified and by the surface area of the embedded length of the bar. **Figure 3(d)** shows the specimen after pull-out test.

2.3. Methodology

Four types of investigation were carried out to understand the influence of different fibers on bond strength of different grades of concrete.

1. Bond strength of different grades of Control Concrete (CC), i.e.; specimens without fibers and without heating.
2. Bond strength of different grades of CC specimens without fiber subjected to elevated temperature (30 min, 60 min, 90 min and 120 min).
3. Bond strength of different grades of FRC specimens without applying elevated temperature.
4. Bond strength of different grades of FRC specimens subjected to elevated temperature (30 min, 60 min, 90 min and 120 min).

The details of the experimental investigation carried out are shown in **Figure 4**.

Figure 3. (a) Specimen after cooling. (b) Pull-out test. (c) Schematic bond stress and slip diagram. (d) Bond failure of specimen.

3. Results and discussion

3.1. Influence of temperature on bond strength of control concrete under elevated temperature

The ultimate failure of specimens of all grades occurred with vertical cracks. This may be due to the development of high thermal stresses inside the concrete specimens which caused the formation of micro cracks within the specimen [35]. At higher temperatures, reduction in strength of concrete is caused due to compression failure of concrete [36]. Figure 5(a–d) show the results of experimental investigation carried out to determine the pull-out bond strength of plain concrete specimens of different grades. It was found that bond strength of concrete decreased with the increase in temperature for all grades. It might be due to formation of cracks, dehydration of C-S-H gel in concrete and bond failure between aggregate and cement paste [37]. Experimental investigation also indicated that the bond strength of specimens

M50: Characteristic Compressive strength of concrete (50MPa).

subjected to heating decreased as the duration of heating increased. The slip value also was found to increase as the duration of heating increased from 30 minutes to 120 minutes. A sudden failure was observed for specimens heated up to 120 minutes (1029 °C) for all grades of concrete. As the grade of concrete increased, bond strength also increased for the specimens with and without fiber. The investigation also showed that cracks began to appear when the temperature reached around 600 °C [3]. The micro cracks were found to be more pronounced at 800 °C and extensively increased at 1000 °C. The specimen completely decomposed and lost its binding properties after exposure to 1000 °C. This was attributed to continuous crack formation [38].

The compressive strength of the specimens also decreased with respect to the loss of bond strength at elevated temperature [39]. The loss in strength of concrete was related to loss of weight of samples since reduction in compressive strength was attributed to dehydration of C-S-H gel in concrete at elevated temperatures [40]. Failure of concrete specimens might occur at elevated temperature, when heating reduced the bond strength between the steel and concrete. Bond failure was usually combined with tensile failure as the tensile strength decreases rapidly with heating [1].

3.2. Influence of addition of fiber on bond strength of concrete (without heat)

Normally synthetic fibers assist in reducing the cracks in concrete elements. For making FRC, fibers are dispersed and distributed randomly in concrete at the time of mixing and thus there could be an improvement of concrete properties in all directions. **Figure 6(a–d)** show the results obtained from the pull-out test to determine the bond strength of concrete specimens with and without fiber for different grades without

exposure to heat. The bond strength of concrete was found to increase with the addition of fibers [41]. Bond strength of concrete with CF had the highest bond strength. Concrete with BF had the second highest strength and that was followed by AF and GF. The bond strength of the concrete with PPF was the least among the FRC. The bond strength was higher for specimens with fiber having higher young's modulus. Addition of fiber was found to improve the splitting tensile strength of concrete also. It was mainly due to the bridging action of the fiber across cracks, which effectively restrained the propagation of micro cracks in the primary stage. The delay in the development of macro cracks improves the splitting tensile strength [42].

The higher strength of concrete with CF may be due to its highest elastic modulus [43]. More over CF has more strength and volumetric stability than BF and GF under severe alkali condition [24]. Carbon Fiber Reinforced Concrete (CFRC) is known for higher flexural strength of concrete than any other fibers [13]. CF is very versatile, because of its extremely high strength to weight and stiffness to weight ratios. CF is highly stable and is relatively non-sensitive to chemical degradation [43].

From the investigations it is observed that bond strength of Basalt Fiber Reinforced Concrete (BFRC) is higher than that of concrete with AF, GF and PPF for all grades of concrete. It may be due to the resistance of BF to most chemicals, alkali solutions and water [44]. When BF comes in contact with other chemicals, no chemical reaction takes place [25]. The previous researchers reported that the addition of BF significantly improves the tensile and flexural strengths [42].

It is observed from the investigation that addition of AF in concrete resulted in more bond strength than GFRC, PPFRC and CC. It may be because of the higher Young's modulus of AF compared to those of GF and PPF. A previous research reported that the presence of strong alkaline aqueous solution can cause degradation of AF [45]. Concrete having a high pH value, possesses a highly alkaline environment [46]. The drop in the tensile strength and the surface degradation of AF is due to an alkaline environment [47]. Thus the bond strength of concrete with AF will decrease with ageing of concrete [1,47].

From the experiments, it is found that Glass Fiber Reinforced Concrete (GFRC) possesses more bond strength than Polypropylene Fiber Reinforced Concrete (PPFRC) and concrete without fiber (CC). It may be due to GF's more elastic modulus than PPF's.

It is found that PPFRC has more bond strength than CC. PPF can improve the flexural ductility and long-term durability of concrete [48]. It also reduces the plastic shrinkage of concrete [49]. It is reported that PPF fills the holes of mortar and thus reduces porosity and also stops the propagation of the micro cracks [50]. This improves the internal tensile, adhesion and bond strengths [51].

3.3. Influence of fibers on bond strength of concrete under elevated temperature

Figure 7(a-d) show the results of the pull-out test carried out on FRC with different grades exposed to duration of 30 minutes (821 °C). Addition of fiber can control reduction in bond strength by reducing macro cracks development on concrete [13,26]. The

reduction in bond strength is high for CC followed by AFRC, PPFRC, GFRC, BFRC and CFRC for all grades of concrete.

It can be seen that, concrete with CF exposed to heat for a duration of 30 minutes (821 °C) exhibits higher bond strength than the concrete with other fibers. CF can resist the volume change of concrete caused by rapid change of temperature due to its negative coefficient of thermal expansion [43]. Hence in the case of CFRC cracking inside the concrete may be prevented [26]. Also CFRC has high bond strength than any other FRC at 30 minutes (821 °C) of exposure to heat. Additionally, CF has the ability to retain its tensile strength even at high temperatures [52].

Similarly BF also has higher elastic modulus, and the bond strength is higher for the specimens even after exposure to heat for duration of 30 minutes (821 °C). The tensile strength and elastic modulus are reduced when exposed to higher temperature, but they maintain their bond strength [15]. It may be due to its high melting point and its natural properties like non-combustible and explosion proof [25]. The reduction in bond strength is found to be higher for PPFRC and GFRC which may be due to low elastic modulus of PPF and GF.

It is observed from the investigation that GFRC has more bond strength than PPFRC, AFRC and CC. The reduction of bond strength of GFRC is higher at elevated temperature. It may be as a result of decrement in Young's modulus of GF with heat exposure [16].

It can be seen from the [Figure 7](#) that the bond strength of PPFRC is higher than that of AFRC and CC. This is due to the fact that PPF turns into vapour above 340 °C [2,17] and forms vapour pressure dissipation network, which dissipates vapour within the concrete and prevents spalling [17,18,53]. This prevention of spalling helps to strengthen the bond between concrete and reinforcement. The escape channels formed by melting of the PPF impart limited improvement in bond resistance against heating because of the reduction in both splitting and compressive strengths as a result of the increase in the overall porosity [19]. Permeability of concrete with PPF is found to increase after heating due to the melting of PPF [54]. This has reduced the risk of increase in pores pressure in the PPFRC, which prevents the propagation of cracks. Thus bond strength reduction is controlled in PPFRC [55].

Observation indicates that the reduction in the bond strength of AFRC is very high at elevated temperature. Earlier researches report that AFRC subjected to more than 150 °C leads to oxidation of AF. More over degradation of AF due to the alkaline environment within the concrete is accelerated by the rise in temperature [47]. Thus AFRC, when heated, loses its bond strength between 50 and 60%.

The bond strength values of the samples heated for 60 minutes (925 °C) are shown in [Figure 8\(a–d\)](#). For all grades of concrete the bond strength decreased with increase in temperature. Observation indicates that at 60 minutes (925 °C) also that bond strength of CFRC is greater than that of other FRC. Bond strength of GFRC was found to decrease considerably. BFRC and PPFRC retained more bond strength (60–85%) than that of other FRC specimens. Bond strength of AFRC significantly reduced and the bond strength was found to be less than that of concrete without fiber (CC). One of the reasons behind the drop in bond strength of FRC can be partly attributed to uneven shrinkage caused by evaporation of water, dehydration and disintegration of

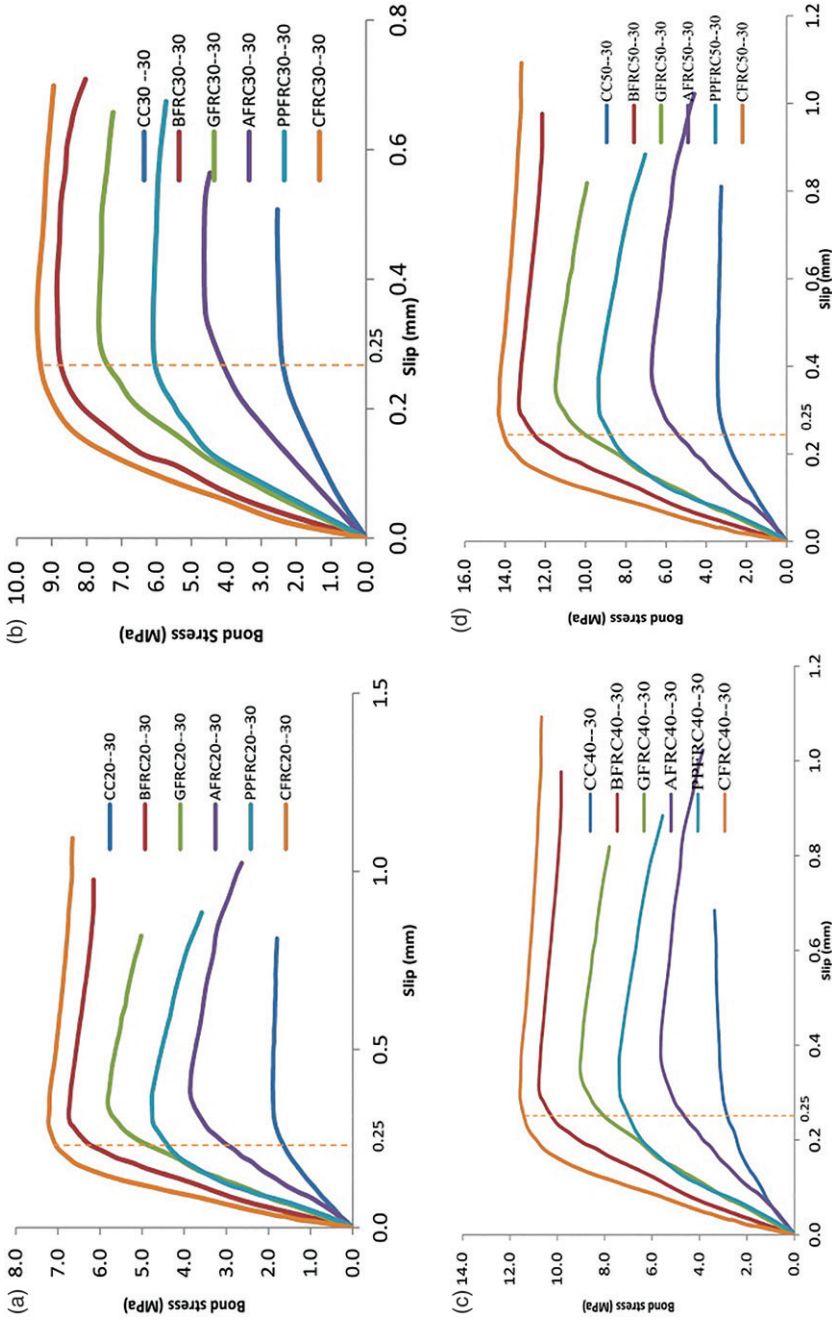

Figure 7. (a) M20 FRC specimen with 30 min heat exposure. (b) M30 FRC specimen with 30 min heat exposure. (c) M40 FRC specimen with 30 min heat exposure. (d) M50 FRC specimen with 30 min heat exposure.

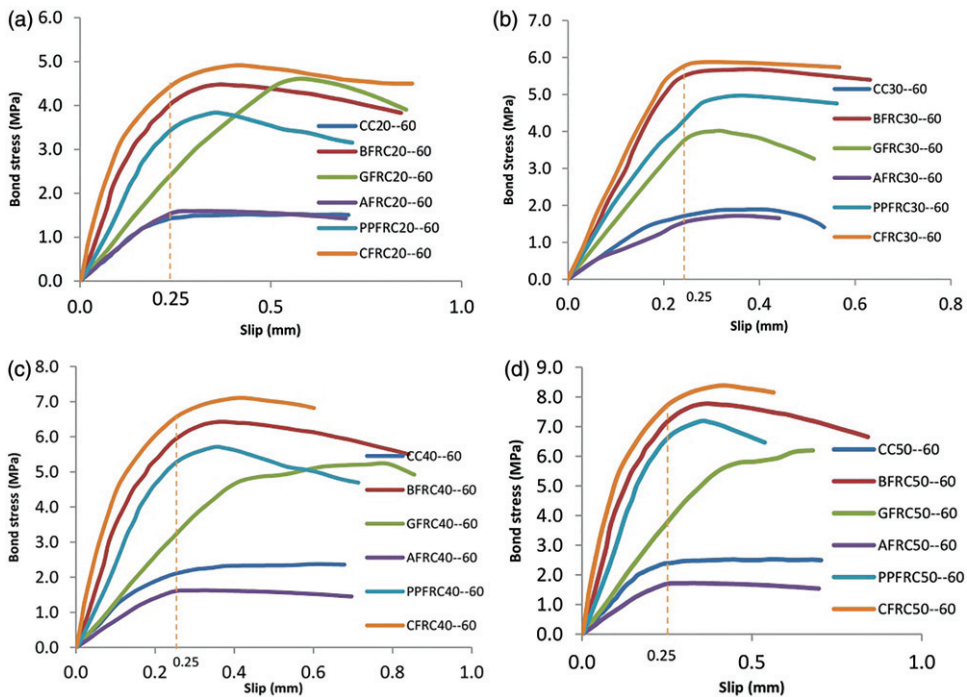

Figure 8. (a) M20 FRC specimen with 60 min heat exposure. (b) M30 FRC specimen with 60 min heat exposure. (c) M40 FRC specimen with 60 min heat exposure. (d) M50 FRC specimen with 60 min heat exposure.

ingredients of concrete at elevated temperature [54]. When the concrete surface is exposed to elevated temperature, surface cracking occurs. As a result of continuous heating, the free water existing within the concrete turns into vapour forming vapour bubbles. In the absence of pore, the vapour within the vapour bubbles induces tensile stress. When the tensile stress exceeds the tensile strength of the concrete, spalling occurs [56,57]. After 60 minutes (925°C) of exposure, the bond strengths of CFRC and BFRC are found to be almost the same. Some research works indicate that after exposure to a very high temperature, the CF completely melts; losing volumetric stability and the GF melts partially. Concrete with BF maintains its shape even after heating and has not lost the volumetric stability. This high thermal stability is due to the material characteristics of natural basalt rocks, which nucleate at high-temperature [24].

Bond strengths of specimens after 90 minutes (986°C) of exposure to heat are shown in Figure 9(a–d). From the observation, the bond strengths of CFRC, BFRC and PPFRFC are found to be almost similar. Bond strength of GFRC is decreased lower than that of PPFRFC. Bond strength of AFRC is reduced far below that of all types of FRCs.

The presence of CF and BF enhance bridging during crack growth in the concrete [2,58]. Hence it is understood from the experimental data that CFRC and BFRC have good bond strength at this temperature. Reduction in bond strength is observed for GFRC at this temperature. It may be due to reduction in elastic modulus of GF with elevated temperature [52]. Reduction in bond strength of each FRC depends on the type of fiber added to it. Exposure to higher temperature always affects the strength of

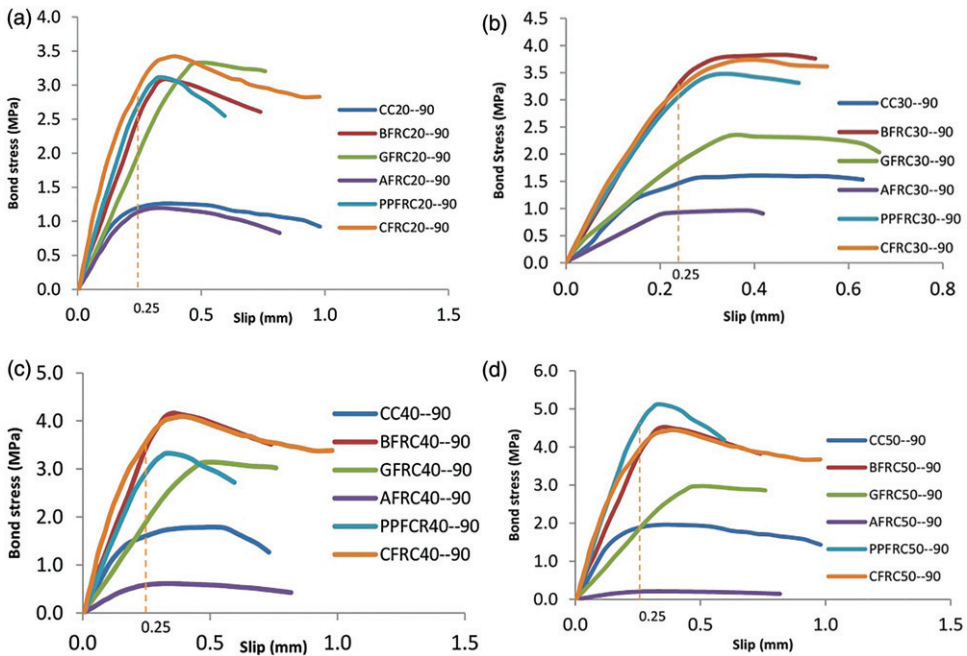

Figure 9. (a) M20 FRC specimen with 90 min heat exposure. (b) M30 FRC specimen with 90 min heat exposure. (c) M40 FRC specimen with 90 min heat exposure. (d) M50 FRC specimen with 90 min heat exposure.

concrete. Continuous heat exposure results in evaporation of water inside the concrete. This will increase the pore pressure and cause severe damage to concrete. PPF melts at high temperature and creates voids for releasing pressure inside the specimen when heated. Hence it helps control the instigation of cracks.

Figure 10(a–d) show the values of the bond strength of FRC exposure for duration of 120 minutes (1029 °C). Considerable loss of bond strength was noticed for all FRC after an exposure of 120 minutes of heat (1029 °C). When FRC was exposed for more than 120 minutes (1029 °C) of heat, the specimens were severely damaged and bond strength was found to be significantly reduced. This severe strength loss might be attributed to the decomposition of hydration products and thermal incompatibility between aggregates, fibers and cement paste [59]. The contribution of fibers at higher temperature is limited in controlling the reduction in bond strength. Concrete with PPF perform better in the case of specimens heated for 90 (986 °C) and 120 minutes (1029 °C) of exposure than the concrete with other fibers. The advantage of using PPF in high strength concrete is more pronounced from the results obtained.

3.4. Influence of grade of concrete on bond strength of concrete under elevated temperature

Figure 11(a–d) depicts the bond strength at a slip of 0.25 mm of FRC and CC for all grades exposed to different durations of heat. The bond strength of concrete is found to improve with the increase in the grade of the concrete. While heating, concrete with higher grades exhibits higher percentage of reduction with respect to its own unheated

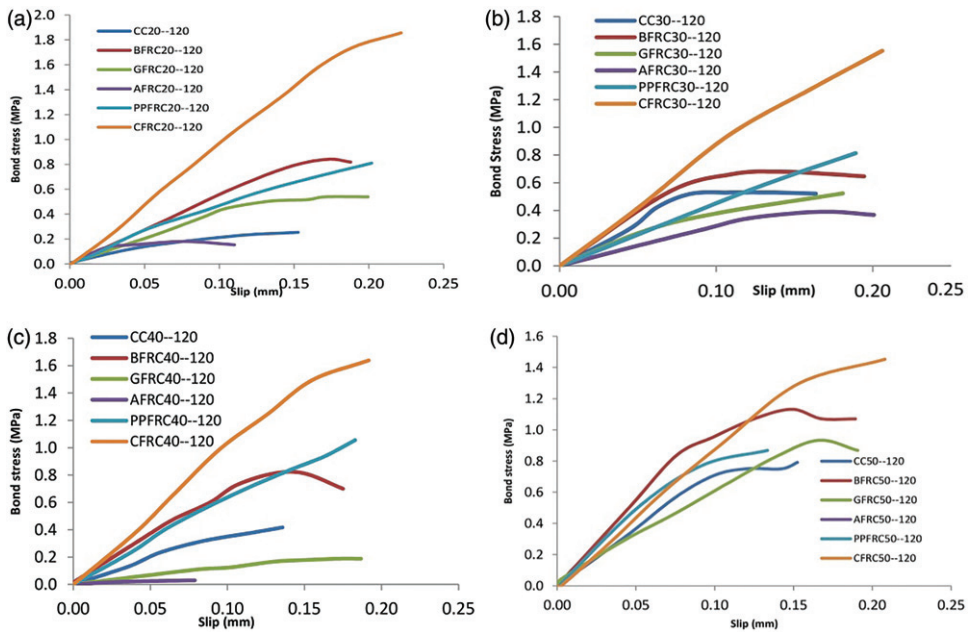

Figure 10. (a) M20 FRC specimen with 120 min heat exposure. (b) M30 FRC specimen with 120 min heat exposure. (c) M40 FRC specimen with 120 min heat exposure. (d) M50 FRC specimen with 120 min heat exposure.

specimen in bond strength (Table 4) [60,61]. Bond strength of all grades of concrete specimens fails to reach slip of 0.25 mm when exposed for duration of 120 minutes (1029 °C). The contribution of PPF begins with 60 minutes (925 °C) exposure of heating for improving bond strength of concrete. This can be visible in the case of M50 concrete specimen exposed to 90 minutes (986 °C) of heating. It may be due to the higher contribution of PPF at elevated heat by creating additional pores in high grade (M50) concrete.

3.5. Development of empirical relation to determine residual bond strength of concrete under elevated temperature

It was observed from the investigation that major reduction in bond strength occurred at a slip of 0.25 mm in most of the specimens. Hence it can be generalized that development of bond stress happens most importantly up to 0.25 mm slip for all the specimens. Table 4 gives the average percentage reduction in bond strength of heated specimens compared with its own unheated specimen. From these observations it was found that all the specimens exhibited 100% of reduction in bond strength for 120 minutes (1029 °C) of heat exposure.

Based on the experimental investigations, a statistical relation has been established to determine the residual bond strength at 0.25 mm slip. Compressive strength of concrete before heat exposure, type of fiber and duration of heating were considered as variables. The Bond Strength ($BS_{0.25}$) can be estimated using the relationship given below, the minimum value of $BS_{0.25}$ shall be considered as zero.

The concrete specimens were exposed to elevated temperature and the bond strength of specimens was found after cooling the specimens. The reduction in the bond strength was calculated. For all the concrete specimens exposed to heat for 120 minutes (1029 °C), the bond strength falls down to zero (0%). The results of thirty specimens were used to determine the relative bond strength of specimens subjected to elevated temperature for durations of 30, 60, 90 and 120 minutes (821 °C, 925 °C, 986 °C and 1029 °C). The relative bond strength is defined as the ratio between the bond strengths of heated and unheated specimen. This relative bond strength is the constant B and the values of B are given in Table 6.

When fibers added to concrete, its bond strength increases or falls depends on the type of fiber and grade of concrete. Table 9 depicts the ratio of bond strength of FRC with respect to bond strength of CC in an unheated condition. It can be seen that for different grades of concrete, the ratio of bond strength is almost same. From Table 9, it is evident that the ratio of bond strength of FRC with respect to CC in an unheated condition is independent on the grade of concrete. The constant C has been obtained based on trial and error method and the values for different fibers are given in Table 7.

Time of exposure (min)	Ratio b/w FRC and CC					
	AFRC	BFRC	CFRC	GFRC	PPFRC	
0	2.3	2.5	2.9	2.1	1.6	
30	1.8	3.7	4.1	3.0	2.5	
60	1.0	2.8	3.1	1.7	2.4	
90	0.9	2.1	2.4	1.3	2.1	

For each FRC specimen, the ratio of bond strength of heated specimen varies according to the duration of heat exposure and the type of fiber. The values of bond strength and the ratio of bond strengths of heated to unheated specimen are given in Tables 10 and 11.

The constant D is defined as the algebraic difference between the ratio of bond strength of FRC and CC at the same temperature. This constant may be positive or negative according to its contribution of fibers. Also this constant is applicable for concrete with grade ranges from M20 to M50. The values of constant D are given in Table 8.

The bond strength of different specimens was estimated using the equation derived and compared with bond strength at 0.25 mm slip.

4. Conclusions

Based on the experimental studies, it was found that the increase or decrease in the bond strength depends on the physical properties of fibers added to concrete specimens. One of the major parameter which influences the bond strength of concrete is the Young's modulus of the fiber. Fiber with high Young's modulus is found to increase the bond strength of concrete. Formation of macro cracks is the main reason for the reduction in bond strength of concrete. Macro crack formation occurs mostly with the rise in the temperature. Addition of fibers helps to control the development and propagation of micro cracks and thus the decrease in the bond strength is controlled. At exposure duration of 120 minutes (1029 °C), the concrete specimens completely disintegrate and the bond strength becomes zero. At this temperature fibers cannot control the micro crack propagation and hence the bond strength of concrete decreases drastically. Some fibers like PPF melt at high temperature and are absorbed by cement matrix, which induces air voids inside the specimens. This leads to reduction in the pore pressure which helps to prevent the formation of macro cracks. Carbon and Basalt Fibers have high melting point and high Young's modulus. These fibers produce a very strong bond among cement matrixes. To break this bond, more stress is needed. Hence use of these fibers helps to reduce the cracks. The contribution

of carbon fiber on increasing the bond strength of M50 concrete is found to be 4.2 times more than that of the controlled concrete. The degradation of AF happens in alkaline environment. Moreover at elevated temperature, AF gets oxidized and disintegrated which leads to accumulation of cracks in AFRC. Young's modulus of glass fiber reduces with increase in temperature which results in the reduction of bond strength of GFRC.

Investigation on Impact Strength of Fiber Reinforced Concrete Subjected To Elevated Temperature

Alwyn Varghese, Anand. N, Prince Arulraj G

Abstract: The effect of elevated temperature on impact strength of Fiber Reinforced Concretes (FRC) is investigated in this paper. Cylinder specimens are used with different types of fibers such as Aramid, Basalt, Carbon, Glass, Polypropylene and PVA. All the specimens were exposed to elevated temperature as per standard fire curve following ISO 834. After heating the specimens are cooled by natural air prior to impact strength test. The tests are conducted as per ACI committee 544. Test result reveals that addition of fiber enhances the impact strength of concrete specimens. Concrete with Carbon fiber and Basalt fiber exhibits better performance than concrete with other fibers. In unheated condition Carbon fiber shows 5.9 times increase in impact resistance with respect to reference specimen. For 90 minutes of heat exposure, all FRCs except concrete with Aramid fiber shows 2 times better impact resistance than that of reference specimen.

Index Terms: Fiber Reinforced Concrete, Impact Strength, Elevated Temperature, Carbon Fiber, Basalt Fiber

I. INTRODUCTION

Concrete is a brittle material due to its higher rigidity. During the past few decades, several experiments had been conducted to improve the ductility of concrete [9-13]. Presently Fiber Reinforced Concretes (FRC) is used in construction industry to overcome the deficiencies regarding the tensile strength of concrete. For better usage of fibers in cement composites, different types of fiber products are also developed [1]. Toughness is an important mechanical property, FRC exhibits higher toughness when subjected to different type of loads. Impact strength can be calculated based on the toughness of the material under impact loads. Previous researches indicates that several investigations and tests have been conducted to analysis the impact resistance of concrete specimens [2- 8]. This paper evaluates the impact resistance of different FRC specimens by impact test and the results are evaluated in terms of ultimate failure impact energy. Concrete structures are affected by a many of risks during their life span, such as earth quake, fire and impact loading etc. When concrete structures are loaded repeatedly as a function of time, severe damages may occur. Blast induced impact and fire always happen concurrently on structural members thereby encircled with a risk of impact load with fire load [14, 15]. Few research works carried out on impact resistance of FRC after the heat exposure. Though some studies have considered mechanical properties of blast induced impact and fire load of concrete structures [14-16], it was not reported the impact resistance of different types of fiber reinforced concrete after exposed to heat. The

objective of the investigation is to evaluate the impact resistance of plain concrete (Reference specimen) with different strength grades after exposed to elevated temperature by standard fire curve [19]

II. MATERIALS AND TEST METHODS

A. Materials and Mix Proportioning

Table 1: Properties of Fiber

Fiber	Melting Category	Density (g/cu.cm)	Melting point (°C)
AF	Low	1.44	150
BF	High	2.65-2.8	1400
CF	High	1.6	1200
GF	High	2.6	1500
PPF	Low	0.90 -0.91	160 - 170
PVA	Low	1.29	220

Concrete specimen used for this investigation consists of plain concrete with fibers. Ordinary Portland Cement (OPC) of 53grades was used to cast all the specimens. Crushed stones of size 20mm were used as coarse aggregate. The 12mm length short fibers which are supplied in bunch are dispersed in concrete mix. Table 1 shows the properties of Aramid (AF), Basalt (BF), Carbon (CF), Glass (GF), Poly Propylene (PPF) and Polyvinyl Alcohol (PVA) fibers that were used in specimens. The volume fraction used for all fibers were 0.25%. A water reducing agent Conplast SP430 was used to improve the workability of the concrete mixtures.

B. Test specimens

Concrete specimen of 150mm diameter and 64mm height were cast. After casting the specimens were kept in the curing tank for 28 days [17, 18] (figure 1). After curing the specimens were dried for 24 hours prior to the test. Specimens were heated up to 30 minutes, 60 minutes and 90 minutes (821°C, 925°C and 986°C) respectively as per Standard fire curve [19]. Heated specimens were cooled by natural air before testing.

Investigation on Impact Strength of Fiber Reinforced Concrete Subjected To Elevated Temperature

The investigation has been carried out for M20, M30, M40 and M50 grades of concrete.

Figure 1: Specimens in Curing Tank

C. Test procedure

Drop weight impact test was carried out on specimens as per the guidelines of ACI committee 544 [17]. Figure 2 shows the concrete specimen and equipment for conducting the drop weight impact resistance test. The equipment consists of a standard manually operated 4.45 kg compaction hammer with a height of 457mm drop on a hardened steel ball of 63.5mmdiameter which is resting on a flat base plate with positioning bracket. The test specimen is then placed on the base plate with the finished face up and positioned inside the brackets. During this testing the hammer was dropped repeatedly and the number of drops required to produce the first visible crack (N1) in the specimen and for the ultimate failure (N2) were recorded.

The impact energy of the specimens was calculated by [20]

$$E = Nmgh \quad (1)$$

Where

E - impact energy,

N - the number of drops,

m - the mass of dropped ball (4.45 kg),

g - the gravity based acceleration (9.8m/s^2)

h - the height of drop (457mm).

Figure 2: Impact Test Setup

III. RESULTS AND DISCUSSION

A. Impact resistance of specimens without heat exposure

It is observed that for the plain concrete specimens (without heat exposure) after the testing the pieces are fractured into separate pieces, whereas the specimens with fiber the pieces damage level was less. This phenomenon may be because of the addition of fiber leads to slow down the crack formation and final failure of the specimen [20]. From table 2 and table 3 it is understood that the impact energy of every FRC specimen increased 4-7 times with respect to the fiber properties than that of the plain concrete. This can be explained by assumption that the fiber enhanced the ductility behaviour of the concrete [20]. Concrete with AF in all grades of concrete shows 5 times increase in impact energy than plain concrete. Concrete with BF and CF shows 6 times increase in impact energy. GF shows least (3 times) increment compared to other FRC's. PPF and PVA fibers shows 4 times increment in the impact energy as compared to that of plain concrete. M50 grade concrete (D series) containing CF possess highest impact energy of 2034N-m and 2733N-m for first crack and ultimate failure respectively. Similarly it was observed for the specimen with BF the impact energy was 2014N-m and 2693N-m. The similar was observed for other grades (A, B and C series) of concrete. The crack bridging property of the fibers is assumed to absorb additional energy and inhibits the sudden failure of specimens. The present investigation findings support the research findings of Mohammad hosseini et al [21] and Mastali et al [22]

B. Impact resistance of specimens with heat exposure

For all concrete mixes, reduction in impact resistance after exposure to elevated temperature was observed. The degradation of impact strength on concrete may be due to the thermal gradient as well as different physical and chemical changes occurred in the concrete [23-26]. Table 2 and Table 3 illustrate the loss in impact strength of concrete with different mixes with reference mix. In the case of 90 minutes (986°C) of

heat exposure, all the specimens broken into pieces with 1-3 number of drops and first crack was formed in the first drop itself. It may be due to the formation of voids and thermal stress formed inside the specimens during the heating process. For the temperature with higher range there were little impact energy exists for the all FRC's. Because at these temperatures bond between the fibers and matrix decreased as the mechanical properties of the fibers reduced [27-28].

Specimens heated up to 60 minutes (925⁰C), the first crack developed with 1-3 hammer drops. But the ultimate failures of specimens were according to the type of fiber added in to it. Concrete with AF specimens suffered with severe degradation at its 3rd drop. When heated up to 30 minutes (821⁰C) a sudden decrement in impact resistance observed for all the specimens with respect to that of plain concrete. The drastic decrease in impact strength is observed for concrete with AF and it was 64% - 67%. The least reduction (21%-27%) in impact resistance was observed for concrete with CF.

specimens exposed to heat exposure. It is clearly visible that the addition of fiber has a direct contribution on impact resistance. For unheated FRC specimens it can be seen that the impact resistance are 3 to 6 times more than that of reference specimen. A drastic drop (5.2 – 14.5 times) in impact resistance can be seen when all FRC specimens exposed to 30 minutes of heat exposure. Concrete with CF has more impact resistance (1.1 – 2.3 times) compared to other specimens in 30 minutes of heat exposure.

C. Impact resistance of specimens based on type of fiber

Figure 3 depicts the impact resistance of various FRC

For 60 minutes of heat exposure CF, PPF and PVA shows similar impact resistance. For 90 minutes of heat exposure, plain concrete and concrete with AF shows least impact resistance (19.95 N-m) whereas concrete with all other fibers exhibit better impact resistance (39.90 N-m).

Figure 3: Impact Energy of different types of specimen

IV. CONCLUSIONS

The impact resistance of plain concrete and various fiber reinforced concretes of different grades with and without heat exposure are investigated. Based on the observations made from the investigation, the following results concluded.

- The addition of fiber enhanced the impact strength of concrete.
- The physical properties of fibers affect the impact resistance. The highest impact resistance is observed for concrete with CF.
- At elevated temperature all the specimens showed negligible variations in impact resistance due to the loss in bond with concrete, i.e. Specimen subjected to 90 minutes duration of heating.
- All the grades of concrete exhibited a similar trend in impact resistance for all the duration of heating.
- AF showed a drastic reduction in impact resistance with increase in temperature.

AUTHORS PROFILE

Alwyn Varghese graduated from VLBJEET, Coimbatore in the year 2009. He completed his master degree in structural engineering from KCT, Coimbatore in the year 2013. Presently, he is pursuing Ph.D in the area of Fire resistance of fiber reinforced concrete under Department of Civil Engineering, KITS, Coimbatore. He has published more than 5 research papers in International Journals and Conferences. His areas of interest are Fire resistance of fiber reinforced concrete, Bond strength of concrete.

Dr.N.Anand graduated from Karunya Institute of Technology and Sciences, Coimbatore in the year 2003. He completed his Ph.D work in the area of Self Compacting Concrete Subjected to Elevated Temperature during the year 2014. Presently, he is working as Associate professor in Department of Civil Engineering, KITS, Coimbatore. He has published more than 55 research papers in International Journals and Conferences. His research areas are High performance concrete, Fire resistance of concrete and Lateral load behaviour of tall structures.

Dr. G. Prince Arulraj graduated from Thiagarajar College of Engineering, Madurai in the year 1982. He secured I rank in the college and II rank in Madurai Kamaraj University. He got his masters degree from IIT Madras in the year 1984. He got his Ph.D degree from IIT Madras in the year 1999. He has published 175 papers in International journals and conferences. His areas of interest are Self compacting concrete, Self curing concrete, Fire resistance of concrete and Concrete with nano materials.

Linear Analysis of a Cryo Propellant Tank

Anu Retnakar¹ Ajin A. S.²

^{1,2}Assistant Professor

^{1,2}Ahalia School of Engineering & Technology, Palakkad, Kerala, India

Abstract— There are many stages for satellite launch vehicles. Among them cryo stages use fuels or oxidizers at low temperatures. Propellants are stored in propellant tanks. Tank will be subjected to pressure loads. A cryo propellant tank having liquid hydrogen was modelled axisymmetrically using ANSYS. Linear analysis is performed on it. From the results it was obtained that the equivalent von Mises stress exceeded ultimate tensile strength.

Keywords: Propellant, Linear Analysis, Yield Strength, Axisymmetric Modeling, Plane 82

I. INTRODUCTION

The fuel and an oxidizer in the launch vehicles are stored in propellant tanks. Common materials used for the tank are aluminum, alloy steel, titanium and stainless steel. Tanks can be spherical in shape, cylindrical in shape with half ellipses at the ends, and in irregular shapes. The tanks having cryogenic propellants should be thermally insulated.

In this paper finite element modelling of a tank containing liquid hydrogen tank is done using ANSYS. Plane 82 element was used for the model. Linear analysis was done in the tank. Hoop, meridional and von Mises stresses and radial displacement in the tank were found out.

II. CONFIGURATION OF LH2 TANK

Since liquid hydrogen is having very low density, tank should be bulky. AA2219 copper rich aluminium alloy is used for the tank. It is cylindrical with spherical end domes. There is a cylindrical shell, end domes, end rings and manhole reinforcement rings for the tank. Fig 1 shows the full tank depicting the parts. Fig. 2 shows a dome petal of the tank. At the weld regions of dome, a thickness of 4.4 mm is provided. Away from welded regions of the dome, thickness is reduced to 2 mm. Fig 3 & 4 shows the developed view (inside) of cylindrical shell & section A-A of cylindrical shell respectively. At the weld regions of cylindrical shell, a thickness of 7 mm is provided. Away from weld regions of the shell, thickness is reduced to 2mm. The cylindrical shell and domes are connected by using Y-shaped rings. Fig. 5 shows the cross section of the end ring. At the centre of fore end dome, a manhole cover is provided. Fig. 6 shows the cross section of manhole reinforcement ring to which the manhole cover is welded.

Fig. 1: LH2 tank assembly

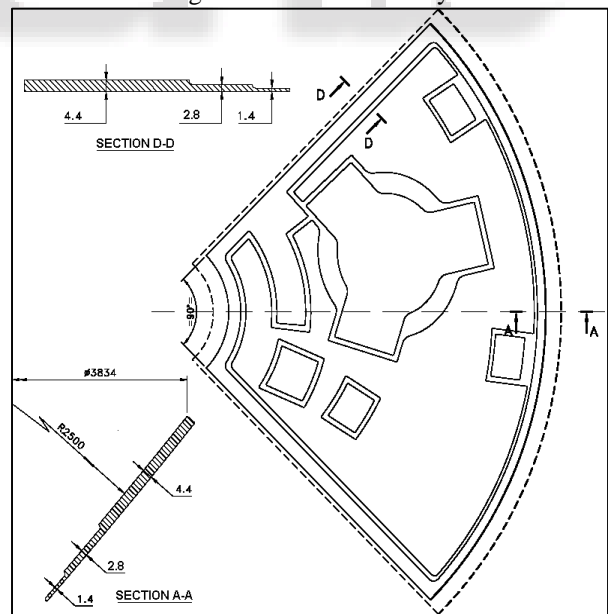

Fig. 2: Typical dome petal

Fig. 3: Developed view (inside) of cylindrical shell

Fig. 4: Section A-A of cylindrical shell

Fig. 5: Cross section of end ring

Fig. 6: Cross section of manhole reinforcement ring axisymmetric modelling

The axis of symmetry is global cartesian Y axis. +X direction is taken as the radial direction. Axisymmetric PLANE 82, 2-Dimensional, 8 noded structural solid elements were used for the model. Only half portion of the tank is modeled because of symmetry. An internal pressure of 3.4 bar was applied. At the global cartesian Y axis, few nodes were constrained in X direction. Also few nodes at the bottom of the aft end ring were constrained in Y direction. The tank with boundary conditions is shown in Fig.7. Fig. 8 shows the internal pressure distribution in the tank. Table 1 gives the material properties of tank.

Property	Value
Young's modulus	71000MPa
Poisson's ratio	0.33
Tangent modulus	1420MPa
Yield strength	350MPa
Ultimate strength	440MPa

Table 1: Material Properties

Fig. 7: FE model of tank

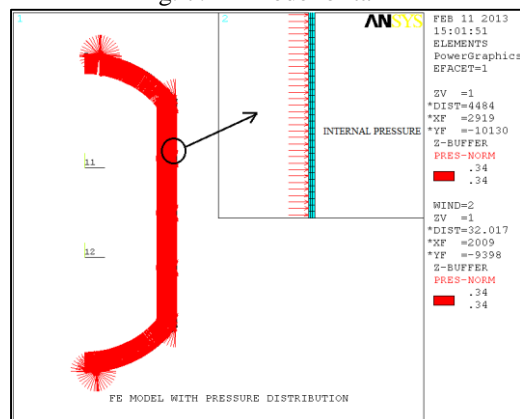

Fig. 8: Pressure distribution results and discussion

After performing the linear analysis following results were obtained. Fig. 9 shows the deformed shape of tank. Fig. 10, 11 and 12 shows the hoop, meridional and equivalent (von Mises) stress plots respectively. Fig. 13 shows the radial displacement of the tank. Table 2 shows the results.

Parameters	Values
Hoop stress	354.813MPa
Meridional stress	160 to 180MPa
Maximum equivalent stress	671.677MPa
Maximum radial displacement	8.244mm

Table 2: Analysis Results

- Maximum equivalent stress is located at the chemical milling step at the manhole to fore end dome portion where thickness variation of 2.8 mm to 1.4 mm was there.
- The hoop stress, meridional stress and radial displacements matched with the classical solution.

Fig. 9: Deformed shape of LH2 tank

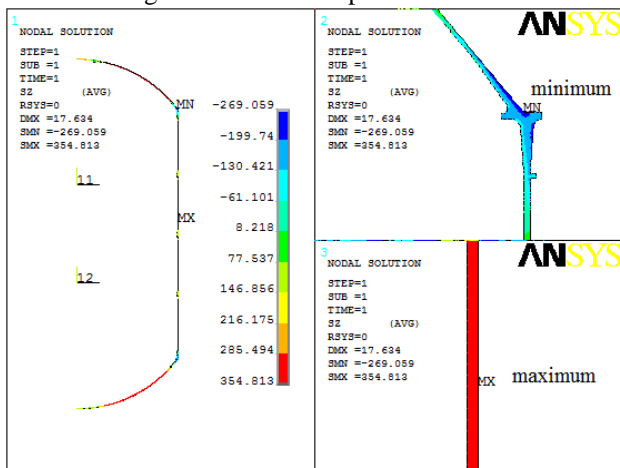

Fig. 10: Hoop stress distribution

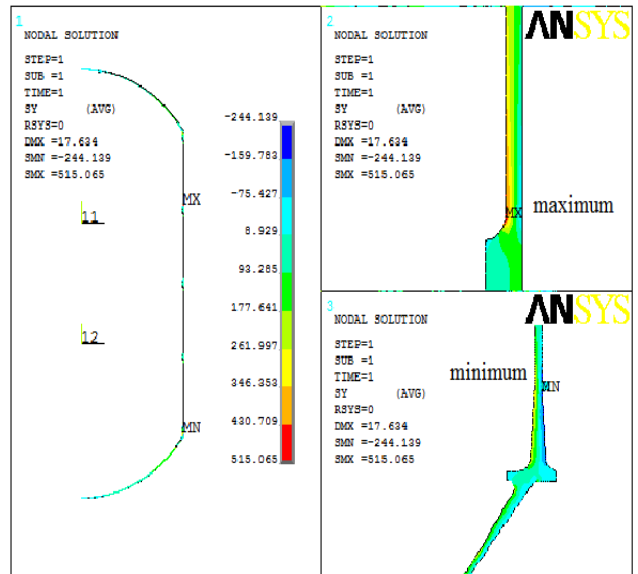

Fig. 11: Meridional stress distribution

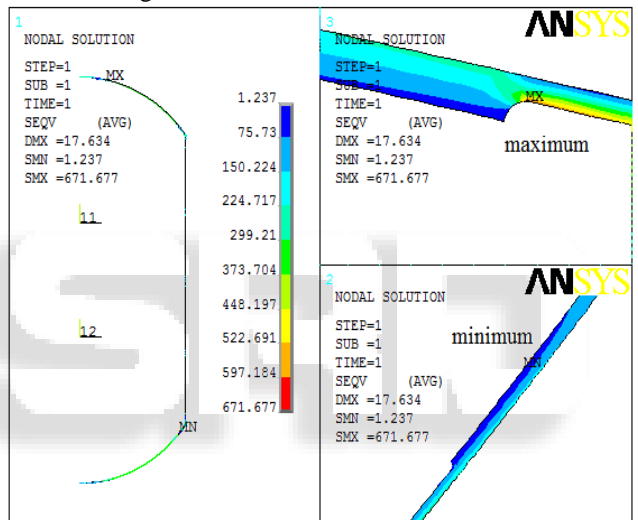

Fig. 12: Equivalent stress

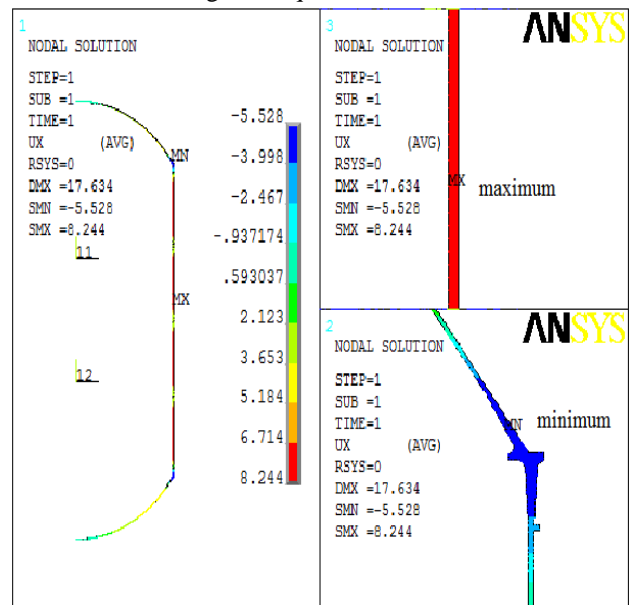

Fig. 13: Radial displacement

III. CONCLUSION

The von Mises stress in the tank is 671.677 MPa. This value is greater than the yield strength of the material, i.e, 350 MPa, as well as the ultimate strength i.e, 440 MPa. The tank is more prone to failure at the chemical milling step in the manhole to dome portion. Therefore as the equivalent von Mises stress has exceeded the ultimate tensile strength, the tank will undergo failure. Hence the tank should be redesigned.

Er Narendra Singh, FIE
President

It is a pleasure for me to recognize the efforts of all concerned who have meticulously planned and worked hard to bring out this wonderful 'Technical Volume' on the occasion of the 35th Indian Engineering Congress held online during 18 – 20 December 2020 on the theme "Engineering for Self-reliance and Sustainable Goals".

The Indian Engineering Congress is the apex activity of the Institution enjoying a special status amongst the engineering fraternity. This is organized every year where professionals and engineers from all the disciplines of the engineering gather to share their knowledge and experience. This year due to the unprecedented scenario of nationwide lockdown to control the pandemic, we had no other way but to organise it on virtual mode. We are really overwhelmed by the response from all over the country and abroad.

This volume comprises of the articles by engineering professionals with rich experience in their discipline. I am sure that the articles in this technical volume will benefit scientist, engineers, technologists, policy makers, academicians and all concerned.

Er Narendra Singh

Prof (Dr) Swapan Bhaumik, FIE

Chairman

Committee for Advancement of Technology and Engineering (CATE)

On behalf of the Technical Committee, I am honoured and delighted to present the prestigious Technical Volume of the 35th Indian Engineering Congress, which was held in virtual mode during 18-21 December 2020. The major theme of this Congress was “Engineering for Self-reliance and Sustainable Goals”. I am excited that despite pandemic, there were huge responses to attend the Mega Event of IEI. On the first day of 35th Indian engineering Congress, there are eight parallel Technical Sessions on virtual mode. Out of 230 papers received, 192 papers were accepted after review. We are thankful to the Reviewers for their kind evaluation of the papers received for 35th IEC, Session Chair and Co Chair of all technical sessions for their relentless effort to conduct the sessions successfully.

I also thank Director (Technical) of The Institution of Engineers (India) and his team for their relentless effort to make the event successful and bringing out this Technical Volume.

ABSTRACT

Owing to an increased demand for dietary food and the reduction of arable land, an alternative solution such as microalgae is recently being exploited. One such viable microalgae candidate for high-value food and protein production is *Spirulina platensis*. The present work reports on the optimum growth, protein and fatty acid content of *Spirulina platensis*. A 23 full factorial central composite design (CCD) was used to estimate the culture involvement variables initial concentration of nitrogen, initial inoculum concentration, and cultivation time to optimize the biomass concentration, protein, and fatty acid extraction from *Spirulina platensis*. This study illustrates that the most influential factor is the cultivation time for optimum biomass and protein content growth. The results found using full factorial CCD indicate that 15 days, 0.1 g/l of inoculum concentration and 0.015 M of initial nitrogen concentration are optimal working parameters to attain a maximum biomass yield of 2.21 g/l.

Keywords : Cultivation; Full factorial design; Microalgae; Protein; *Spirulina*.

ABSTRACT

Algae have allured global attention in the last two decades due to high-value proteins, commercially potential natural products, polyunsaturated fatty acid, coloring agents, which can be used in diversified fields [1–4]. Algae can be categorized as either microalgae (micrometers to tens of micrometers) or macroalgae (large, a few millimeters to plants up to 4 m high). Microalgae studies have been performed since the 1950s: particularly *Spirulina* sp., *Dunaliella* sp., and *Chlorella* sp. are used for the production of valuable chemical elements, protein, lipids, vitamins, antioxidants, fuel production, and wastewater treatments [5–8]. Microalgae are extremely adaptable due to their distinctive capacity to grow under different environmental conditions, such as wastewater, saline water, brackish water, as well as freshwater [9]. The microalgae biomass growth curve shows the sigmoidal growth shape phenomena [10–14].

The blue-green cyanobacterium microalgae *Spirulina platensis* are the simple microscopic and primordial life forms on earth. It may be 10 micrometers in diameter and 60–300 micrometers long. Generally, it is available in tropical and subtropical areas living alkaline waters, lakes and ponds. *Spirulina* grows very well in basic water (pH 9–11) since other microbes did not survive in an alkaline environment [15]. The tribes of Chad lake in Central Africa used *Spirulina* as functional food from ancient times [3,16–19]. *Spirulina* contains high protein (approximately 60% – 70 %), essential fatty acid, vitamin contents, lipids, carbohydrates, minerals such as zinc, iron, calcium, magnesium, sodium and potassium [20]. *Spirulina* based products, such as powder, tablet or capsule and supplements, are manufactured in Japan, Israel, Thailand, India, Taiwan, Mexico, the USA for the food market [8,21]. *Spirulina* has been effective for cholesterol-lowering, anti-cancer, anti-allergic, anti-viral, antioxidant, anti-inflammatory, and the treatment of arsenic poisoning. *Spirulina* is called the future food of the earth and named as “Superfood” by the World Health Organization. It was effectively used for astronauts on space missions, according to the European space agency, Japan Aerospace Exploration Agency (JAXA), and NASA [22]. Besides, this research work on microalgae related topic matches the 9 of 17 goals of the United Nations SDG. These goals are SDG—1: Zero poverty, SDG—2: Zero hunger, SDG—3: Good health and wellbeing, SDG—7: Renewable energy, SDG—8: Good Jobs and economic growth, SDG—9: Innovation and infrastructure, SDG—12: Responsible consumption, SDG—14: Life below water, and SDG—13: Climate action.

Spirulina platensis biomass production depends on many factors such as high pH values (9–10), light, temperature, nutrient concentration, magnetic field, light, speed, length of cultivation, solar radiation, season and inoculum cell concentration [23–26]. Nitrogen is the key nutrient that contributes to the cultivation of *Spirulina* biomass. In this research, one of our targets is to find the answer to the question: How these environmental factors affect the growth rate of *Spirulina* and its protein content and amount of fatty acid?

The objective of this study was to illustrate the influential factors of the fast cultivation of *Spirulina platensis*. In this analysis, (I) duration of cultivation, (II) initial nitrogen concentration, and (III) initial inoculum concentration of algae are considered predicted factors during the cultivation time. We also analyzed the growth development of biomass concentration of *Spirulina platensis* and the amount of protein and fatty acid content.

METHODS

In this study, a full factorial central composite technique is employed for the growth of *Spirulina sp.* High and low levels are studied regarding primary experiments [27]. This study evaluates three factors, such as the length of cultivation, initial nitrogen concentration and initial inoculum concentration for the biomass concentration, protein (%), and fatty acid (%) content. The upper and lower level of cultivation time is 20 to 15 days, initial nitrogen concentration is 0.03 to 0.015 M, and initial biomass concentration is 0.2 to 0.1 g/l.

Design of Experiments for 2³ Factorial

A full factorial technique is an eminent procedure to establish the effects of variables on a particular response. This method can be applied to minimize the number of trials in which several variables must be studied simultaneously. Furthermore, it can be used to three main effects (independent factors), three two-way interaction effects, and a three-way factor interaction and a constant term. A 2³ full factorial design with maximum and minimum levels and three factors were performed using statistical software Minitab to observe the factors for biomass concentration, protein and fatty acid content.

A full factorial design demonstrates the assessment of all possible combinations. So, the full factorial method is best for a small number of parameters. To analyze the parameters a mathematical model was used, which determines the correlation between the response and the main factors (C, N, I). This mathematical model can be expressed by a polynomial equation model, as shown below:

$$Y = \alpha_0 + \alpha_1 N + \alpha_2 C + \alpha_3 I + \alpha_{12} NC + \alpha_{13} NI + \alpha_{23} CI + \alpha_{123} NCI$$

Where Y is the response, α_0 is the constant; α_1 , α_2 and α_3 are coefficients of the main variables N,C and I, respectively; α_{12} , α_{13} and α_{23} are coefficients of the effects of the two-way interaction; α_{123} is the coefficients of three-way interaction effects. Let, N, C, and I are three variables at two levels $N_0, N_1; C_0, C_1; I_0, I_1$, respectively. The all possible combination of predicted variables can be written as:

Table 1: Possible combination of a factorial experiment

(1)	(N)	(C)	(I)	(NC)	(NI)	(CI)	(NCI)
$N_0 C_0 I_0$	$N_1 C_1 I_1$	$N_0 C_1 I_0$	$N_0 C_0 I_1$	$N_1 C_1 I_0$	$N_1 C_0 I_1$	$N_0 C_1 I_1$	$N_1 C_1 I_1$

RESULTS AND DISCUSSION

In this research, a 2³ factorial experimental technique was employed to find the consequences of the variables cultivation length (days), initial concentration of nitrogen (M), and inoculum concentration and their interaction effects on the production of biomass concentration, protein and fatty acid content.

Pareto Chart of the Effect of Variables

Pareto diagram shows the magnitude and significance of the effect of variables. It describes the absolute value of the effects and depicts the reference line (red line in Fig.) on the graph. The horizontal bars that cross the red reference line are statistically important. Bar chart 1(a) shows that the interaction CI and factors I and C are most significant for fatty acid content. In **Fig. 1(b) and 1(c)**, factor C is the most prominent factor for biomass concentration and protein content. Moreover, the three-way interaction effect NCI (Initial nitrogen concentration, cultivation time, and initial inoculum concentration) are not statistically significant, which is shown in **Fig. 1(c)**.

Main and Interaction Effect of Variables

The main effect plot is used to evaluate the relative strength of the effects of individual factors. The magnitude describes the strength of the effect, and the sign of the main effect explains the direction of the effect. **Fig. 2(a) and 2(c)** describes the same relation for the biomass concentration and protein content between the factors of nitrogen concentration and cultivation time. Interactions effect plot illustrates the response of two variables at all probable arrangements of their settings. In **Fig. 2(b) and**

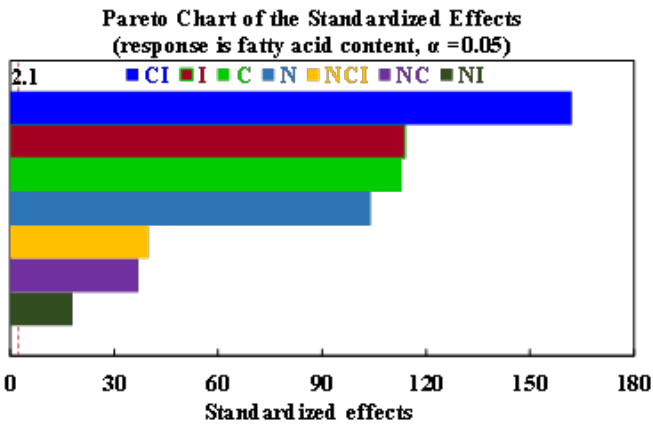

Fig.1(a): Standardized effect on the fatty acid content

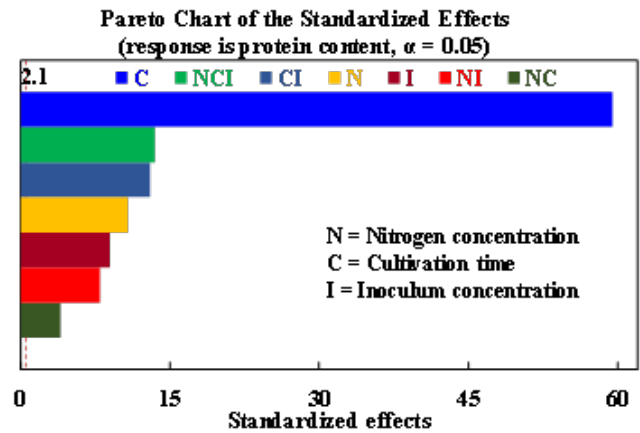

Fig.1(b): Standardized effect on protein content

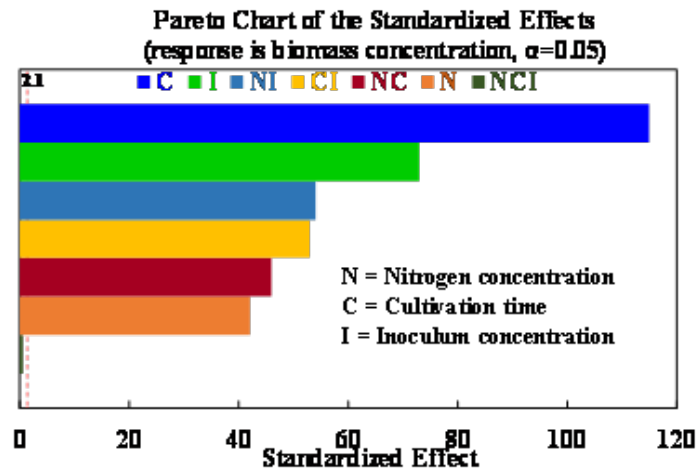

Fig.1(c): Standardized effect on biomass concentration

2(d), it shows that the interaction effect between nitrogen and inoculum concentration for biomass and protein content is greater than fatty acid content (Fig. 2(e)).

Residual Plot

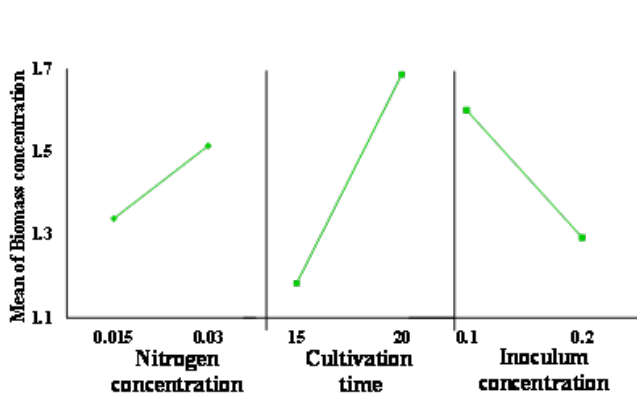

Fig.2(a): Main effect of biomass concentration

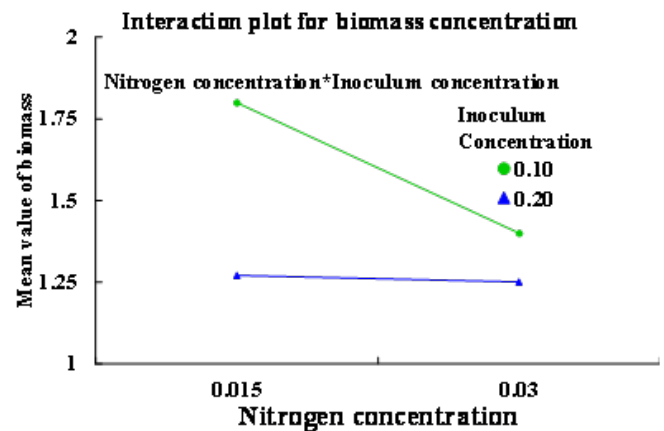

Fig.2(b): Interaction effect of biomass concentration

Fig. 2(c): Main effect of protein extraction

Fig. 2(d): Interaction effect of protein content

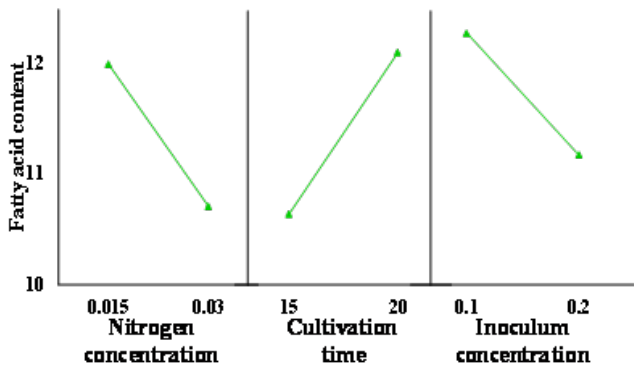

Fig. 2(e): Main effect of fatty acid content

Fig. 2(f): Interaction effect of fatty acid concentration

Fig. 3(a), 3(b), and 3(c) are residual plots for biomass concentration, protein and fatty acid content, which are suitable tools for model justification. To find the standardized residual, we use the following equations:

Residual = observed value - predicted value.

The normal probability plot of residuals shows that all the points in Fig. 3 fall on a straight line approximately. So, the residuals for the response variables almost fitted the normal distribution.

Analysis of Variance (ANOVA)

The influence of each parameter is a key element in the production of biomass concentration, protein content and, the amount of fatty acid. Analysis of variance was employed to investigate the results of the research and to estimate how much deviation was promoted by each factor. Different level of variables acknowledges the main factors and their interaction impacts.

Protein and fatty acid contents, which are affected by various factors from the ANOVA technique, were shown in Table 2.

The impact of variables is statistically significant if the p-value less than 0.01. To have a better understanding of the variables, computer-generated main and interaction effects were investigated since any individual element possibly interacts with any or all the factors. From Table 2, it is explored that all linear, 2-way interaction effects and 3-way interactions effects are statistically significant for fatty acid and protein content. It is also studied that all effects are statistically significant for biomass concentration (data not shown). It is illustrated that the adjusted sum of squares of cultivation length (C) is the highest (1752.07)

Fig.3 (a): Normal probability plot of residuals of biomass concentration

Fig.3 (b): Normal probability plot of residuals of fatty acid content

Fig.3 (c): Normal probability plot of residuals of protein content

for protein content. But for fatty acid content, inoculum concentration (I) and cultivation time (C) have the same adjusted sum of squares (approximately 11.7). For two-way interaction effects, cultivation time, and Inoculum concentration (CI) has the most adjusted sum of squares on the production of fatty acid (24.32) and protein content (85.05). The consequence of each coefficient determined by p-values are listed in table 2. All the parameters are significant for linear, 2-way interactions, and 3-way interactions model: the smaller the p-value, the more influential the corresponding coefficient.

The production of biomass was modeled employing the following equation:

$$\text{Biomass (g/l)} = - 1.400 - 28.67 * N + 0.11600 * C + 19.300 * I + 4.800 N * C - 313.3 N * I - 0.9000 * C * I + 1.33 * N * C * I$$

Adjusted and predicted R-squared values computed for protein content were 0.9945 and 0.9913, and for fatty acid content was 0.9997 and 0.9995, respectively. These values are rational for each other.

Contour Plot for the Biomass Concentration, Protein and Fatty Acid Content

In this work, the contour plot illustrates the correlation between the independent (initial nitrogen concentration (M), duration of cultivation (day), and initial inoculum concentration (g/l)) and dependent (biomass concentration (g/l), fatty acid (%), and

protein content (%) factors. Contour maps are a method to describe a 3-dimensional surface on a 2-dimensional plane. In this method, x and y-axes represent the predictor variables and response variable z as contours. It is a technique to illustrate a 3-dimensional surface on a 2-dimensional plane. In Fig. 4(a), 4 (b), and 4(c) shows the contour plot for biomass concentration, 4(d), (e), and (f) shows the fatty acid content, and 4(g), (h) and (i) depicts the protein content in the same set of axes. Biomass concentration is more than 1.75 g/l when inoculum concentration at a minimum level (0.10 g/l) and duration cultivation is

maximum level (20 days). Biomass concentration is increasing when the duration of cultivation time and nitrogen concentration increasing.

CONCLUSIONS

The 23 full factorial technique gives easy and feasible results for the three variables at two levels. This study is allowing not only the main effects of initial nitrogen concentration, cultivation time, and inoculum concentration, but also providing clarifications of the 2- way and 3-way interactions, including these variables. The major effects of the three variables are examined from ANOVA tests. The most potential variable is the length of cultivation for the maximum growth of *Spirulina platensis*. The interaction between cultivation time and inoculum concentration is significant for the synthesis of fatty acid.

Fig4. Contour plot of (a) inoculum concentration and cultivation time, (b) nitrogen concentration and cultivation time, (c) nitrogen concentration and inoculum concentration for biomass concentration (g/l), (d) inoculum concentration and cultivation time, (e) nitrogen concentration and cultivation time, (f) nitrogen concentration and inoculum concentration for fatty acid content (%), (g) inoculum concentration and cultivation time, (h) nitrogen concentration and inoculum concentration, and (i) nitrogen concentration and cultivation time for protein content.

ABSTRACT

A comparative study was conducted to evaluate the performance of time based automatic drip irrigation system and manual hose irrigation in okra. Irrigation time optimized at 15minutes provided 250 ml of water per plant. Based on the growth stage of the crop water requirement of vegetables was estimated to be 0.6 to 2 litre/day. To meet this water requirement, irrigation was done at 4 intervals i.e., twice in the morning and twice in the evening twice in such a manner that 1 litre water was irrigated per grow bag. Thus drip irrigation conserved 50% water compared to manual hose irrigation. It was found that drip irrigation gave 70% higher yield than the yield obtained with the manual irrigation system. Automatic DIS increased irrigation efficiency up to 95% than that of conventional method of irrigation.

Keywords : DIS; Water use Efficiency; Crop yield.

INTRODUCTION

Kerala, blessed with lot of rivers and good rains, gets an average annual rainfall of 3000 mm per year. During the South West monsoon Kerala receives 90% of rains; bulk of which is not utilized due to surface runoff owing to undulating topography. Urbanisation, which has resulted in shrinkage of cultivated area, together with unavailability of water during off seasons has led to shortage of quality produce in the state. Shortage of local produce leads to import from nearby states.

In India good volume of agricultural produce occurs. About 500 million tons of vegetables need to be produced by 2050 (As per survey of Government of India, 2001). In order to meet the target, agriculture has to be taken up in a big scientific way and in this process, water demand goes up. It would be as high as about 85-90% of the total available water. The demand for water from other sectors too would increase multiple folds due to which water allocation for farming may come down to only 75% of what would be required (Sivanappan, 1987). In our country, while irrigation resources are limited, the water use efficiency is very low. In this context, the best approach is implementation of drip irrigation system wherever possible, that makes use of providing optimum quality of water to the plant root thereby enhancing the water use efficiency along with reduction in its wastage. In India, drip irrigation technologies were introduced in the 1970s from countries like Israel and the USA, where it is widely used in large farms. Micro irrigation system has become popular in India and it has been adopted on 400,000 ha. Maharashtra leads in area under drip irrigation covering almost half the total area, followed by Andhra Pradesh, Karnataka and Tamil Nadu. The extent of drip irrigation has increased from almost zero in 1970 to 1000 ha in 1985 and to about 400000 ha in 2002 covering about 30 crops in India.

Owing to high cost of vegetables in the market and general awareness on use of organic produce, a new breed of urban farmers have emerged who have started using their house's roof top for cultivation with plants in grow bags. Many urban farmers are either old and have great difficulty in using the stairs to reach the terrace for watering their plants or are severely short of time owing to their hectic office schedule. Irrigation method used for grow bag cultivation is either hose irrigation or bucket irrigation in which there is large wastage of water. In order to improve the water use efficiency, plant irrigation may be carried out through drip system with the help of micro tubes, though the technology is slightly costly.

Micro irrigation is an expensive venture. The social acceptability is also a decision making factor. Its large scale adoption involves a crucial question of economic viability. In recent times, farmers have been compelled to opt for this advanced method of irrigation, due to limited availability of water resources and high demand for water from all sectors. In spite of the technical and economic feasibility of drip irrigation, its adoption on large scale is not so encouraging in India. There are some limitations in the prevailing methods of drip irrigation like economic investment, clogging of drippers, low awareness level (16%) and inadequate knowledge about its application, utility, method of operation and maintenance.

Keeping in view of the above few facts, a field experiment was conducted on automatic drip irrigation for grow bag cultivation to evaluate yield, water-use- efficiency and economic feasibility of a commonly used vegetable, okra. Comparison was done with the manual hose irrigation for grow bags.

REVIEW OF LITERATURE

In micro irrigation sector, manual interventions are automated to perform all operations, starting from watering to fertigation as per prescribed schedule. Development of automated system has resulted in lot of developments in crop production like improvement in water saving, increase in crop yield, enhancement in water as well as fertilizer use efficiencies and greater benefit cost ratio as well, in comparison to general micro irrigation system (Suresh, 2010). Automated timer based system is comparatively cheaper and hence gaining more popularity than the volume based system (Rajkumar et al, 2008).

In one study on tomato crop (Carpena, et al. 2003), automated irrigation system with feedback from soil moisture sensors resulted in 73% reduction in water use, when compared with standard commercial practices, without any effect on the yield.

Drip irrigation also gave the highest yield with 319 mm of water use as compared to surface irrigation and drip irrigation system with LLDPE plastic mulch increased yield by 57 % over surface irrigation with same quantity of irrigation water. Similar results have been obtained by Tiwari et al. (1998a) for okra crop at Kharagpur, West Bengal. Paul et al. (2013) conducted a study on drip irrigation with plastic mulching; this system increased yield by 57% and net seasonal income by 54%. Sivanappan et al.(1987) conducted a study on drip irrigation for okra and the result revealed that water saved was as high as 84.7% and noted a slight increase in yield by 7.6%.

MATERIALS AND METHODS

This study was conducted for two years (2016 and 2017). About 150 units of drip irrigation system (DIS) had been installed at different locations in the urban areas of Thiruvananthapuram Corporation. This was indeed a turning point for agriculture in urban and peri-urban areas. Nowadays urban people take due care by cultivating vegetables in their roof – top, because of high pesticide residues in market produce. But urban farming initiatives lack supervision and guidance in cultivation practices especially in irrigation. Here comes the role of low cost drip irrigation to solve acute water shortage and labor problem.

Automated DIS helps to irrigate plants in an automated manner. In drip irrigation, water is applied drop by drop to the root zone area of the plant for its effective utilization. This is a precise form of irrigation and helps to manage water resources in an efficient way. Main advantage of this system is that the time and duration of the irrigation sequence can be programmed with very little or no manual intervention. The benefits of embracing this technology are less dependency on labour, smooth operation and energy savings. Each plant will get 1ltr.of water in 1 hour. Dripper discharge rate is 4ltr. / hr. The system contains screen filter that ensures that the emitter does not get clogged. The advantage of this system is that its durability is at least five years and enormous savings in water use as only required water will be used for irrigation and that wastage of water can be minimized.

In summer, plants face severe water stress and water shortage and this will lead to them to permanent wilting point. Absence of irrigation affects vegetative growth which directly influences the crop yield. The closure of stomata is the first symptom of plant water stress. This is followed by plant wilting and finally damage of the plant through overheating. Crop loss occurs once plant wilting occurs. In order to avoid such situations, part time cultivators and aged people can easily adopt the DIS technology for irrigation. Being a labour enhancing technology, automatic drip irrigation avoids man power utilization for watering the plants at the right time, right quantity, right place and right manner. **Table 2** show the cost of the equipments used for the drip irrigation

1) Drip kit :- Drip kit consists of 16mm LLDPE lateral (15 m length), dripper / emitter (4 LPH), stake 4 way assembly with micro tube, screen filter (100 μ efficiency), fittings and accessories.

2) Automatic digital timer:- The mainstay of an automated DIS is the operating time. Automatic timer is a lifesaver in a DIS. Battery powered timers let you to set the frequency and duration of watering schedules for different applications. With automatic shut-off, you can set the timer and be at peace. We can pre -set eight programmes in a timer for all days of the week. Out leads from Timer must be connected to switch board and in leads to the Timer to the pump. Installation and maintenance of the system is simple and easy to use. Water requirement decides the operation time. The controller clock is set for the current day and time. While in operation, as the controller clock time coincides with the start time of the programme, signals are sent to the valves and the sequence of operation is initiated and accordingly the pump gets switched on and off at the specified time. Timer is basically 230VAC with 8 on/off provision having an output rate of 2Amperes.

3) Booster pump:- Pump is essential when the tank is kept on the terrace floor. In order to obtain the necessary discharge, a minimum pressure of 1 kg/cm² is necessary. A 35W submersible pump can lift water up to 3m with a maximum discharge rate of 500 lph. If the tank is above the ground level at a height of more than 2m, having a pump is optional as water flows down due to gravity alone. If pump is used, a 16mm lateral may be connected to the pump to obtain the sufficient pressure.

Drip kit, Digital timer and pump typically used in a DIS is given in **Fig. 1**.

Fig. 1: Dripkit, Timer and Pump of DIS

Fig. 2 gives the schematic of installation of DIS. Submersible pump must be immersed in water tank and timer connected to the circuit. The main line Φ 16mm LLDPE pipe is directly connected to a 35 watts pump to lift the water from the tank. The main unit is connected to a screen filter and control valve. The lateral is provided with on line turbokey dripper of 4 ltr/hr discharge capacity. Four-way assembly with 4 micro tubes are fitted on dripper and tubes were inserted into the 4 grow bags. Fifteen drippers can irrigate 60 grow bags with a discharge rate of 1LPH / Poly bag when the grow bags are arranged side by side. If they are arranged 45cm apart an additional 10m lateral is needed to cover 60 grow bags. Screen filter, filter the water efficiently @ 700 litre per hour. Drip kit will last for more than five years without any fail.

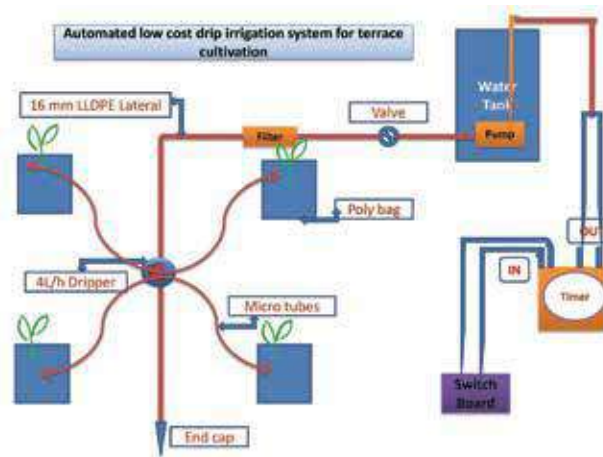

Fig. 2: Schematic of Automated DIS

4) Operation procedure:- Irrigation rate was 250ml of water per plant for 15 minutes. Since the crop water requirement of vegetables is 0.6- 2 ltr./day, irrigation was applied daily for 1 hour. Drip irrigation was applied more frequently in 4 irrigation intervals due to the slower water delivery rate of the drip system.

5) Crop yield:- The yield was recorded for three crop seasons. Weight of vegetables obtained from 60 grow bags has been measured as the total crop yield.

6) Water use efficiency:-Water use efficiency was determined using (1),

$$Eu = C/Wc \quad (1)$$

Where C= Crop yield in Kg/Wc

Wc = Water consumed by the crop in ha cm per Unit area

Since the drip irrigation was used for grow bag vegetable cultivation; based on the experimental study conducted by Babu.G.R,

et.al (2015), the consumptive water use for okra was fixed as 309.8 mm for drip irrigation and for manual irrigation 535 mm based on the study of Sivanappan et.al (1987).

7) Irrigation Scheduling:- The crop requires adequate moisture in the soil during summer months for faster growth. Drip irrigation is most suitable to the crop as it provides uniform moisture throughout the season. The daily water requirement of okra crop is 2.4 l/day/4 plants during early growth stage and 7.6 l/day/4 plants during the peak growth stage. The irrigation system should be operated daily for 75 minutes during initial growth stage and for 228 minutes during peak growth of the crop with an emitter capacity of 2 lph. Irrigation on each day or on alternate days with On-line type of drippers is preferred.(Tiwari.,2015)

8) Economic analysis:- Benefit-Cost ratio and net profit were carried out to determine the economic feasibility of the crop using surface and drip irrigation as suggested by Tiwari et al. (1998a).The fixed cost of the drip irrigation system was Rs.3750/ unit. The useful life of the drip system was considered to be 5 years. The system cost was evaluated by distributing the fixed cost of system over life period of drip irrigation set. In addition to this the cost of cultivation includes expenses incurred for grow bags, porting mixture, intercultural operation, fertilizer, crop protection measures, irrigation water and harvesting with labour charge.

Fig. 3: Automated DIS after installation at terrace of farmers

RESULTS AND DISCUSSIONS

Experiments were conducted to study the crop response and growth of vegetables under automated drip irrigation at 5 plots. Fig. 2 shows the automated DIS installed at two houses. Water was applied equally in all bags. Germination was highest in grow bags that were irrigated through DIS. Plants responded to DIS so much so that flowering in drip irrigated bags started a month earlier than controlled bags (those being watered manually using hose). The yield was recorded for three crop periods. The yield obtained per plant, for okra, was 215kg in drip compared to hose irrigation.

1) Water use efficiency:- On an average, water consumption was observed to be 50 % less compared to conventional irrigation. The amount of water required was further less during rainy seasons. Irrigation was programmed for 15 minutes duration at four different timings to meet the per day water requirement of 1ltr/ plant. Table 1 gives the water use and yield for drip irrigated and control methods for cultivation of okra (average of two year period).

Table 1 : Water use and yield in drip irrigated and control method

Plot no.	Water use efficiency (t/ha ^{-cm})		Yield (Kg/60 nos. of polybags)		% increase in yield
	Control	Drip	Control	Drip	
1	2.34	6.62	125	205	64
2	2.30	6.29	123	195	51
3	2.06	6.08	110	188	70
4	3.08	6.94	165	215	30
5	1.77	6.10	95	189	98

It may be observed that maximum water use efficiency was observed to be 6.94 t/ha-cm at plot 4 compared to hose irrigation. The water use efficiency between conventional and drip irrigation is given in Fig. 4.

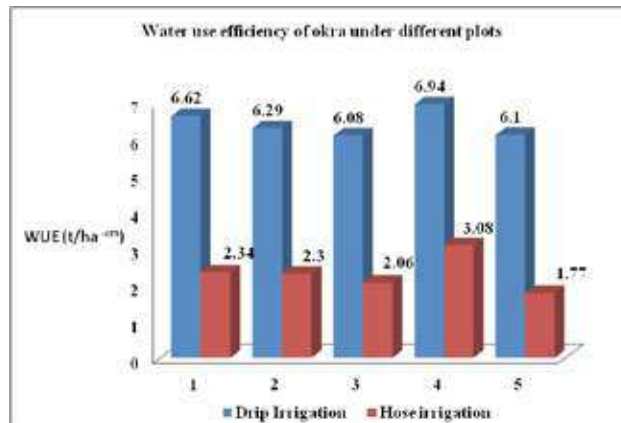

Fig. 4: Water use efficiency of DIS and hose irrigation during cultivation of okra at five terraces

2) **Irrigation efficiency:-** During manual irrigation, about half the amount of water supplied is lost by leakage, overflow and also through evaporation. The irrigation efficiency is only 50%. Using timer based automated DIS, water saved was as high as 95%. Quantity of water used for 4 drip irrigations was 1-2 litres/plant against 5 - 10 litres in conventional method.

3) **Yield:-** As observed from Table 1, maximum yield obtained was 215kg for 60 numbers of poly bags compared to conventional irrigation for three crop seasons. As the discharge rate increases, crop yield also increases substantially (Fig.8). The yield of okra under drip irrigation gave 30 -98% more yield compared to conventional method of irrigation by overcoming severe moisture stress.

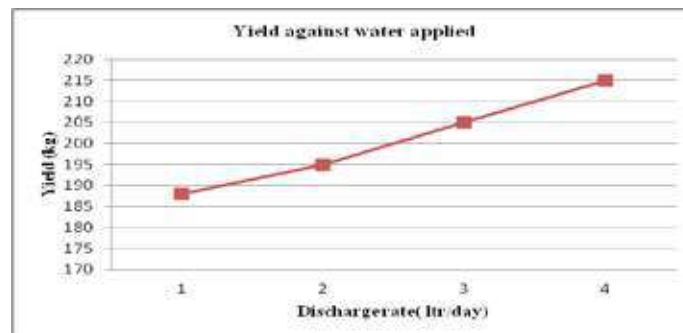

Fig. 5: Crop yield with water discharge

4) **Water savings:-** It was observed that there was substantial water saving ranging from 70 to 90 per cent compared to conventional hose irrigation.

5) **Economic feasibility:-** Maximum net return of Rs.3425 for 60 grow bags with B:C ratio of 1.54 was recorded at P4 and lowest net profit of Rs.1845 for 60 grow bags with B:C ratio of 1.25 in P1 (Table 3). At the same time for conventional irrigation net income varies from Rs. 250 – 575 for 60 grow bags with B:C ratio 1.04 to 1.08. The lower B.C ratio is attributed to lower yield as a result of improper irrigation and thereby low gross income.

Table 2 : Water use and yield in drip irrigated and control method

Plots	Drip				Control			
	Gross cost	Gross income	Net income	BCR	Gross cost	Gross income	Net income	BCR
P1	7380	9225	1845	1.25	5200	5625	425	1.08
P2	6680	9750	3070	1.45	6150	5800	350	1.06
P3	6000	9400	3400	1.56	5500	5250	250	1.04
P4	6250	9675	3425	1.54	7425	6850	575	1.08
P5	6500	9450	2950	1.45	4750	4500	250	1.05

CONCLUSION

Timer based Automatic Family Drip System (FDS) is observed to be user friendly, economical and cost effective as compared with conventional hose irrigation for farming on terraces in cities. 70% increase in yield was obtained against 6.08 t/ha-cm water use efficiency. Water savings to the tune of 50% was observed for drip irrigation by avoiding the wetting of terrace with overrun water loss. Time savings, low energy consumption and low pressure low cost DIS had been widely accepted among urban farmers to promote vegetable cultivation in their own houses.

ABSTRACT

Drying of agricultural products is an important unit operation in the post-harvest phase. It is a thermo-physical and Physico-chemical operation by which the excess moisture in a product is removed. It makes the product suitable for safe storage and protects them against attacks of insects, molds, and other micro-organisms during storage. However, the absence of appropriate preservation techniques and non-renewable energy sources can cause significant production losses that would be prevented by the execution of solar drying devices. The objective of the study is to construct, develop, and validate a double collector solar dryer with improved drying performance. In this present work, the solar dryer was designed based on the design consideration for the Chennai location. The system consists of a primary collector with a V-Corrugated absorber plate which is attached to a drying chamber and the secondary collector is placed on the roof of the drying chamber. And this collector gives an extra thermal source, which indirectly transfers heat to the chamber through a metal plate. This also compensates for the thermal energy loss in the drying chamber. The double collector solar dryer achieved the collector efficiency of 38.23% with an average drying rate of 1.55 g/min for *Andrographis paniculata* (Nilavembu).

Keywords : Solar drying; V-Corrugated absorber plate; Double Collector; *Andrographispaniculate*.

INTRODUCTION

Every year tonnes of agricultural produce gets blemished due to the lack of infrastructures such as cold chain, transportation, storage facility, and inadequate food processing. The study conducted by the Central Institute of Post-Harvest Engineering and Technology (CIPHET) reports that 16% of produced fruits and vegetables in India are being wasted every year [1]. To avoid agricultural losses, preservation techniques must be adopted. Drying of agricultural products is an important unit operation under the post-harvest phase[2] and it should be chosen in such a way that it should be energy-efficient, economically viable, and eco-friendly. Thus, food processing through solar energy helps in the food supply for the growing population.

Solar energy is radiation emitted by the sun that can produce heat and if harnessed, it has the potential to satisfy the world's energy needs. This energy is a form of renewable energy because of its inexhaustible nature, and it can be a substitute for fossil fuels. It can be utilized for applications like solar- water heating, space heating, distillation, pumping, drying, cooking, power generation, etc. Since the price of fossil fuel was not fixed and it has environmental concerns, it creates the users to switch to renewable energy.

Open sun drying is the traditional method of food drying but it has negative impacts such as slow drying rate, dust contamination, and susceptibility to insects and birds. To overcome these impacts, advanced drying technologies were developed and one that kind is drying in a closed chamber by supplying hot air. The solar dryer is preferred over other conventional dryers due to more energy consumption. It can be classified based on the airflow and the solar radiation received by the product. And the main three categories are direct, indirect, and mixed mode of drying. In direct solar drying, the products are exposed to solar radiation through a transparent cover. In the indirect modes of solar drying, the product is not directly exposed to solar radiation. For this, the hot air required for drying is provided through an air heater. In some instances, a solar dryer combines both direct and indirect mode of drying as a single system and that type of drying is known as a mixed mode solar dryer. In this, the product receives heat from the indirect sources (air heater)and the radiation falls through the transparent cover.

Andrographis paniculata also known as Kalmegh or “King of Bitters” is used in traditional medicines[3]. This herb helps to treat chronic and infectious diseases. The aerial parts of the plant (leaves and stems) are used to extract the active phytochemicals and thus used for its medicinal importance.

Srisittipokakun N, Kirdsiri K et.al.,(2012)[4]conducted solar drying experiments of *Andrographis paniculata* (AP) in Nakhon Pathom, Thailand using a newly designed parabolic-shaped solar tunnel dryer which consist of a flat-plate solar collector and a drying tunnel. The total area of the collector was 108 m². The performance of the dryer was investigated by drying 100 kg of *Andrographis paniculata*. The dryer used the leaves of 75% (wb) moisture content, and they dried for 2-3 days to reach safe moisture level of 7% (wb) with a drying air temperature in the range of 35 - 75°C which depends on the weather conditions. The products being dried in the dryer got the heat from both the sunlight and the collectors.

Md Azharul Karim et.al.,(2005)[5] developed a v-groove solar air collector for drying applications and their experimental results indicated that, it is 12% more efficient compared to a flat plate collector. Considering the efficiency of the collector and the outlet temperature, author recommended a flow rate of 0.035 kg/m²s for most drying uses.

Shahrbanou Shamekhi-Amiri et.al., (2018)[6] investigated the thin-layer drying behavior of lemon balm leaves in an indirect-mode solar dryer with forced convection. To enhance the heat gain of the air heater, a counter- flow double-pass packed bed wire mesh layer was configured. The outlet temperature of the collector varied from 38°C to 68°C. While increasing the flow rate from 0.006125m³/s to 0.01734m³/s, it improved the collector thermal efficiency by ~ 20%; further increasing the flow rate to 0.034378m³/s had an undesirable effect on the collector efficiency.

El-Sebaai A A, and Shalaby S M, (2013)[7]designed and fabricated an indirect-mode forced convection solar dryer using double pass v-corrugated plate solar air heater and the thermal performance of the solar dryer was experimentally investigated. Drying experiments were performed for thymus and mint at an initial temperature of 29°C and the final moisture contents for thymus and mint were reached after 34 and 5 hr, respectively. The maximum temperature of the thymus and mint was 51°C and 47°C, respectively.

Hee, Y.Y. and Chong, G.H (2015)[8]Hempedu bumi (*Andrographis paniculata*, AP), also noted as king of bitters. It is commonly found in Asian countries and used for medicinal purposes. In this study, the drying behaviour of AP was investigated at a different temperature of 40, 50, and 60°C with vacuum pressures of 10 and 30 kPa. From the results, it is revealed that the drying time is significantly altered by temperature and pressure. The moisture diffusion's effective diffusivity and active energy were 10-13 m²/s and 33.4 kJ/mol, respectively.

The work on solar drying of *Andrographis paniculata* is less and to improve this, a double collector solar dryer with V-Corrugated absorber plate was developed. The performance of the dryer was experimentally evaluated and presented.

MATERIALS AND METHOD

Experimental Setup

A double collector solar device was designed for Chennai, Tamil Nadu, (13.0827°N, 80.2707°E). This device has two collectors (primary and secondary collectors),that is made up of mild steel. The primary collector is a single pass air- heater with a top glass cover of 5 mm thick and has a V-Corrugated absorber plate with an area of 1 x 2 m and inclined based on the latitude of the region, i.e., 13degrees. The absorber plate fabricated was using aluminium. The outlet of the solar air heater was attached to the bottom of the drying chamber. The chamber consisted of three trays where the products to be dried are kept. And the chamber was insulated by glass wool to avoid heat losses. The dimensions of the drying chamber are 0.530 x 0.355 x 0.9m.

The performance of the solar dryer is based on the heat transfer characteristics of the air heater. The heat transfer characteristics is relied on the absorber plate.

Fig. 1: Experiment setup of Double Collector Solar Dryer

Thus, the area of the absorber plate of the primary collector was increased with the limited space by using V-Corrugated absorber plate ($\theta=60^\circ$). According to this concept, the heated air from the outlet of the primary collector enters the bottom of the drying chamber and moves to the successive trays of the chamber. While doing so, it removes the water content from the products and at the same time the hot air that moves to the further trays will have reduced temperature and this causes uneven drying. To avoid so, the roof of the drying chamber was conceived with a secondary collector. This absorbs the radiation through a glass cover and transfers the heat to the metal plate of the collector. Thus, it indirectly transfers the heat to the products and by this additional heat, the temperature of the chamber can be maintained in all the trays and therefore even drying can be obtained.

Product Characteristics

The product used in this study is the *Andrographis paniculata*, a medicinal herb. This plant is widely found in Asian countries and it is used to cure many infectious and chronic diseases. For the experiment, fresh leaves of about 189g were used for each test. In the morning, the leaves were loaded manually in the trays and during the experiment the leaves were weighed at an interval of time and the temperature in each tray was measured by Thermocouple Type T (range -270 to 370°C).

ANALYSIS

Thermal performance of solar collector

The useful heat gained by the collector is given by,

$$Q_u = m \dot{\square} \times C_p \times \Delta T \quad (1)$$

Where Q_u is useful heat gain (W), $\dot{\square}$ is mass flow rate (kg/s), C_p is specific heat capacity of air (J/kgK), and ΔT is temperature difference (K).

The collector efficiency can be calculated by using following equation,

$$\eta = \frac{Q_u}{I \times A} \quad (2)$$

Where η is the efficiency of the collector, I is solar insolation (W/m²), and A is the area of the collector (m²).

B. Drying curves

Moisture content on the wet basis which is the weight of water per unit initial weight of matter is given by,

$$MC = \frac{w_i - w_f}{w_i} \times 100 \quad (3)$$

Where MC is moisture content on wet basis, w_i is the initial weight of the product (kg), w_f is the final weight of the product (kg).

Drying Characteristics are given in terms of weight at regular intervals of time and drying rate at an interval of time. As mass remains conserved, the drying rate is given by the difference in weight at regular interval of time. Mathematically, drying rate shall be written as,

$$DR = \frac{w_t - w_{t+\Delta t}}{\Delta t} \quad (4)$$

Where DR is the drying rate (g/min), w_t is the weight of the product at time, t (kg), $w_{t+\Delta t}$ is the weight at regular interval of time (kg), and Δt is the time interval (min).

RESULTS AND DISCUSSION

The experiment was conducted at Anna University, Chennai, Tamil Nadu during the month of February and March of the year 2020 and the drying characteristics of *Andrographis paniculata* (Nilavembu) was investigated. The thermal performance of the collector and the drying characteristics such as moisture content and drying rate of different samples were calculated.

Temperature Profile of the Solar Collector

The temperature profile of the solar collector such as the inlet, outlet and the drying temperature was plotted with respect to the solar radiation is shown in **Fig. 2**. As the solar radiation increases the temperature increases and once the radiation falls the temperature tend to decrease. From the **Fig. 2** it has been observed that the outlet and drying temperature are almost maintain the same range and thus temperature loss is minimum, therefore the drying rate can be increased. The average temperature difference between the inlet and the outlet was 16.3°C. The maximum drying temperature achieved in the drying chamber was

plotted with respect to the solar radiation is shown in **Fig. 2**. As the solar radiation increases the temperature increases and once the radiation falls the temperature tend to decrease. From the **Fig. 2** it has been observed that the outlet and drying temperature are almost maintain the same range and thus temperature loss is minimum, therefore the drying rate can be increased. The average temperature difference between the inlet and the outlet was 16.3°C. The maximum drying temperature achieved in the drying chamber was 64°C at 1079 W/m².

Fig. 2: Variation of Temperature vs Solar Radiation

The temperature profile of the drying chamber was plotted in **Fig. 3**. From the **Fig. 3**, T₁, T₂, and T₃ represents the lower, middle, and upper tray of the drying chamber and T_{in} indicates the inlet temperature. Initially the temperature of the three trays were varied and latter, the temperature was almost remained same in the trays due the addition of the secondary collector and this has compensated the temperature loss in the chamber. The highest temperature was obtained in the lower tray because of the primary collector effect.

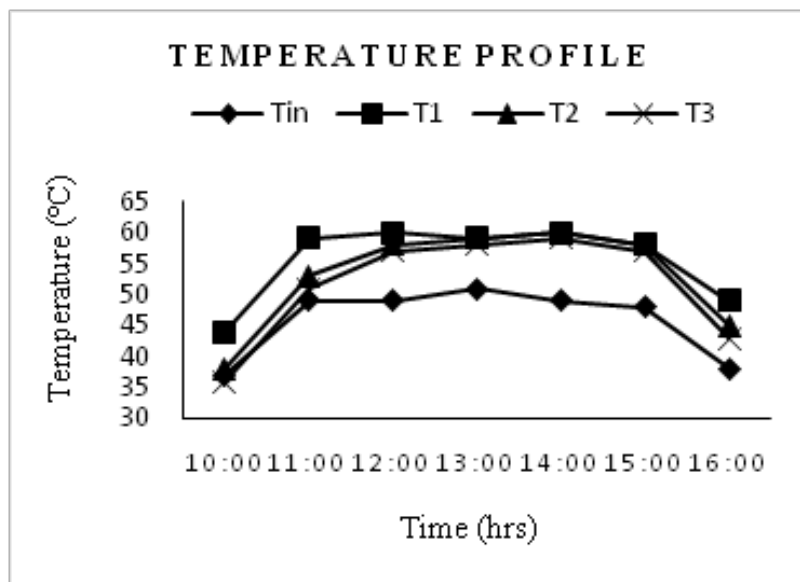

Fig. 3: Temperature profile of the drying chamber

Drying Characteristics

The fresh *Andrographis paniculata* leaves of about 189 g was placed in the trays of drying chamber. The reduction in the weight was observed at a regular interval of time during the day. The weight of leaves in the chamber was reduced to 21g in 3hours during this solar drying. The initial moisture content of the leaves was 78.12% and that of the final moisture content was 11.11 %.

Fig. 4: Fresh Vs Dried *Andrographis paniculata* leaves

The variation of drying rate with respect to time was shown in the Fig. 5. Initially, the rate of drying was faster due to the rapid fall of moisture content and this starts to decrease as the sample loss more moisture and thus the drying rate was slower at the final state. The average drying rate of *Andrographis paniculata* was 1.55 g/min and that of maximum drying rate was 2.5 g/min at the temperature of 52°C.

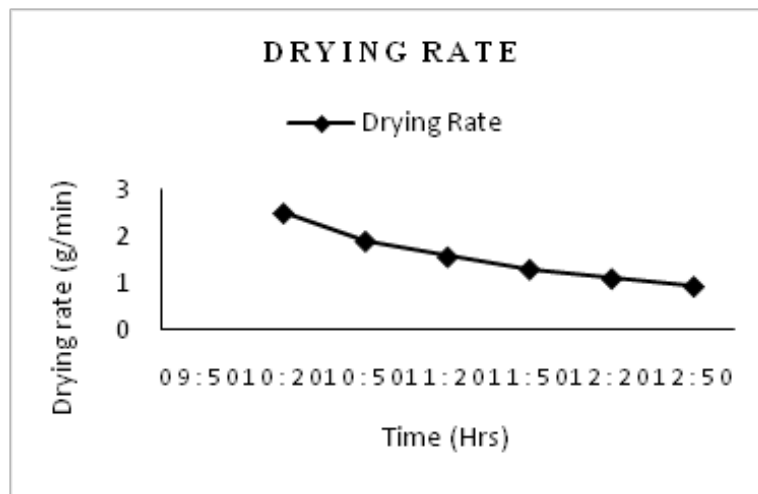

Fig. 5: Variation of Drying Rate Versus time for *Andrographis paniculata* leaves

CONCLUSION

Drying is an ancient technique that has been used to preserve agricultural products. The solar drying system utilizes solar energy to heat the air and to dry any food substance, which is not only beneficial, but also it reduces the wastage of agricultural products and helps them in preservation. It also makes the transportation of such dried products easier and promotes the health and welfare of the people. During this study, the fabrication of a double collector solar dryer was done based on the calculated geometry. The main aim of the project was to develop a solar dryer to reduce the drying time and improve the efficiency of the solar dryer.

The following are the deliberations made by conducting the performance evaluation of the double collector solar dryer with V-corrugated absorber plate:

- Efficiency of the double collector solar dryer with V-Corrugated absorber plate was 38.23%
- The addition of secondary collector on the roof of the drying chamber, improved the drying process and maintained the even drying in the chamber.
- Further the addition of secondary collector on the roof of the drying chamber reduced the space required for drying and hence with limited space more drying process can be carried out.
- The average outlet temperature and the drying air temperature obtained was 56.8°C and 55°C, respectively.
- The sample of fresh *Andrographis paniculata* leaves of about 189 g were placed in the drying chamber and it reduced to a weight of 21g in 3 hours with an average drying rate of 1.55 g/min. and thus the drying rate was improved, and the time taken for drying also reduced.
- This type of dryer is more efficient than that of the normal flat plate collector solar dryer.

ABSTRACT

Jute is one of the important cash crops grown in India by small and marginal farmers of Eastern and North Eastern states. Among several natural fibre crops, jute comes next to cotton in use and trade. Sowing of jute is the most important farm operation for getting healthy and dieses less crop for higher fibre production. Based on spatial characteristics of jute seed and considering the social and economic aspects of jute farming community, a light weight manually operated drum seeder was designed and developed. The transparent drums are having 12 nos. of seed metering orifices or holes at equal interval of 30.0 mm to achieve plant to plant distance of 50-70 mm and row spacing of 250 mm as per the agronomic recommendation. From the experiments, it was found that the seed requirement was 2.8-3.0 kg/ha against 6-7 kg/ha in broadcast sowing. The effective field capacity at mean speed of 1.6-2.0 km/h was 0.18-2.0 ha/h i.e. about 6 hours per hectare with field efficiency of 90-95 per cent. The sowing of jute with drum seeder followed by mechanical weed control using cycle weeder/ nail weeder showed 60 % reduction in manual labour requirement compared to broadcast sowing with increase in fibre yield of 20-22 per cent.

Keywords : Jute; sowing; drum seeder; performance evaluation; effective field capacity; field efficiency.

INTRODUCTION

Jute is an important environment friendly fibre producing crop and its fibre is the second most important textile fibre next to cotton [1]. It provides direct or indirect employment to small and marginal farm families and also jute industry workers. The total area under jute cultivation in India is about 8 lakh hectare and it is mainly grown as a rainfed crop followed by paddy. Due to suitability of climate and soil, the crop is cultivated mainly by small and marginal farmers of Eastern states of India. Method of sowing is the most important farm operation in jute farming for getting healthy and dieses less crop for higher fibre production. The crop yield is affected by type and variety of seed, their emergence and plant density in the field [2]. Jute is mostly sown at the advent of pre-monsoon showers in the month of March and April. To utilize the limited soil moisture availability due to summer rainfall, the farmers follow mostly broadcast method of sowing. In practice farmers use a higher seed rate (6-7 kg/ha) than recommended seed rate due to small size seeds. The weeding and plant protection measures are major problem due to scattered and higher plant density [3]. To maintain optimum plant population in the field, excess 75-80% of the emergent seedlings are removed during weeding and thinning operation at 21-45 DAE. About 15 % of total energy of 10904.1 MJ/ha and about 30-35 % of total cost of production is consumed in the weeding and thinning operation. Further, due to uneven plant population and higher plant density, the overall fibre yield reduces about 10-15 per cent. The line sowing of small seeds using seed drill saves precious seed, ensures depth of placement, germination and reduced cost of sowing and weeding [4]. The seed drills available commercially for small seeds, use sophisticated pneumatic metering mechanism and are costly [5]. Farmers being poor with minimum land holding do not permit them to have seed drills. They are therefore bound to follow the traditional practice of broadcast sowing and face difficulty in intercultural operations and overall management of their crop. As the yield rate is low, farmers derive marginal benefit out of their produce [9]. Considering the socio-economic condition, nature of land holding of farmers, a low cost and light weight manually operated four row drum seeder for sowing jute and other small seeded up-land crops has been designed and developed at ICAR-Central Research Institute for Jute and Allied Fibres (ICAR-CRIJAF), Barrackpore, Kolkata. The developed implement is able to reduce drudgery in seed sowing operation and reduction in cost of cultivation with higher productivity. The present study was undertaken to evaluate the seed pattern characteristics of seed rate deviation, seed distribution and economics of developed manual drum seeder.

MATERIALS AND METHODS

The physical and morphological characteristics of the promising variety, JRO-204 (Suren) jute seed of were measured in the laboratory. Using these seed characters and other agronomic information, shape and capacity of seed drum, no. of seed

dispensing orifices of metering mechanism and distance between metering orifices were determined [6]. The wall thickness of seed drum was determined by the bulk density of the seed. The shape and size of seed dispensing orifice were determined by trial and error method taking seed rate into account for obtaining plant population.

The average length, breadth and thickness were found to be 2.07 mm, 1.20 mm and 1.10 mm, respectively. The test weight, bulk density and angle of repose were measured to be 1.92 g, 0.74 g/cc and 27.25 degree, respectively.

Description of the drum seeder

The manually operated drum seeder mainly consists of seed drum-cum-dispenser, main shaft, ground-cum-transportation wheels, frame, furrow openers and covering device “**Fig. 1**”. The conical frustum shaped seed drum is fabricated with light weight, durable and transparent material for visibility of seed. Drilling of seed on the furrow happens during the movement of implement through the seed dispensing orifices on the seed drum at equal interval of 30.0 mm to achieve desired plant to plant distance of 30-50 mm in the field [7]. The hoe type furrow openers are present ahead of seed box at equal spacing of 250 mm [8]. The bigger size ground wheels of ϕ 304.8 mm fabricated with mild steel flat with 12 nos. pegs are used for easy movement of implement without slippage on tilled soil. A single chain made of mild steel is attached besides the seed drums for covering the drilled seeds on the furrow. The implement consists of a compacted and height adjustable handle. It can be adjusted according to the height of operator for easy operation and reducing the drudgery during operation. The drive shaft is attached with two sealed bearings for easy movement during operation. The technical specifications of the implement have been presented in **Table 1**.

Fig. 1: Drum seeder for jute

Laboratory test of drum seeder

The drum seeder was calibrated in the laboratory as per BIS test code for seed rate. Seeding uniformity was tested on a bed of 5 m x 1 m size prepared in the field with a thin white cloth lying on the top. A thin layer of grease was applied on the cloth to prevent displacement of seeds from line while falling from seed box. The drum seeder was operated on the prepared seed bed using plain ground wheels of same dimensions like spiked ground wheel at walking speed of 1.6-2 km/h. Number of seeds per meter of bed was counted and uniformity of seed distribution along the line was calculated using “(1)”.

$$S_e = 100 (1 - \frac{Y}{D}) \tag{1}$$

Where,

S_e = Seed distribution efficiency of drum seeder;

Y = Average numerical deviation of number of seeds per meter from average number of seeds per meter length;

D = Average number of seeds per meter length.

Table 1: Technical specifications of drum seeder

Parameter	Values
Overall dimensions	
Length	1046 mm
Width	1000 mm

Height	1000 mm
Weight	14 kg
Ground drive details	
No. of wheels	Two (m.s. flat)
Effective diameter	304.8 mm
Lug height	45 mm
Seed metering	Gravity fall
Drum capacity	Vol. 0.001 m ³
Row spacing	25cm
No. of rows	4
Suitability of crop	Jute, mustard and sesame
Seed covering mechanism	Chain type (L=1680 mm)

Field performance test of drum seeder

The field experiment for sowing of jute seed (JRO-204) using manual drum seeder was conducted in the ICAR-CRIJAF experimental field as per BIS test code. The soil at the experimental site was sandy loam having sand, silt and clay in the ratio of 74.8, 13.2 and 11.8 per cent, respectively. The tests were replicated thrice in plot size of 20 m x 10 m. The field observation like speed of operation, depth of seed placement, effective field capacity and draft were recorded and mean observations were taken. A direct reading type spring dynamometer was used to measure the pull of drum seeder. Draft of the drum seeder was computed taking angle of pull. The power required to pull the implement was calculated using “(2)”.

$$\text{Horse power (hp)} = \frac{D \times S}{75} \quad (2)$$

Where,

D = Draft of the implement, kg;

S = Speed of operation, m/s.

Labour requirement, field efficiency and power requirement were computed from the observed field data as per BIS standard. The seed pattern characteristics were observed after germination of the seed under field condition and compared with broadcast sowing.

RESULTS AND DISCUSSION

Laboratory test of drum seeder

The calibration of the drum seeder was carried out in laboratory for jute. There was variation in seed rate at different seed drum conditions i.e. full filled (400 g), ¾ filled (300 g) and ½ filled (200 g) due to unequal size of seeds. The minimum 2.61 kg/ha and maximum seed rate of 4.37 kg/ha was observed with full filled and ½ filled seed drum. The optimum seed rate of 3.48 kg/ha was observed at ¾ filled seed drum, which was significantly lower than the recommended seed rate of 6-7 kg/ha for broadcast sowing. Thus, around 50 per cent reduced seed rate may help in reducing the cost of cultivation in terms reduction in labour cost for weeding and thinning operations.

No mechanical damage was observed due to absence of mechanical metering mechanism and gravity flow of seeds from seed drum. Minimum and maximum number of seeds dropped per meter was 55 and 73. The seed distribution efficiency varied from 60 to 70 per cent and found decreased with increase in speed of operation.

Field performance test of drum seeder

The field performance of the drum seeder was carried out at the ICAR-CRIJAF Farm, Barrackpore “Fig 2” and results are presented in Table 3. During the test the mean actual seed rate was found to be 2.8-3.0 kg/ha. The lower seed rate obtained may be due to skidding of ground wheel during operating in the field. The depth of seed placement was varied 10 mm to 15 mm. The operational speed of implement in the field varied from 1.6 -2.0 km/h. Effective field capacity (EFC) of drum seeder varied from 0.18 to 0.20 ha/h, thus one hectare could be sown in 5-6 hours only. Average field efficiency was found to be 90-95

per cent. Draft of the implement was calculated taking height of the handle from ground during the operation. The angle of pull was found to be 39.350. The draft was varied from 72.71 N to 95.35 N with an average of 85.02 N. The power requirement was varied from 37.3 W to 46.56 W with an average of 41.93 W, which could be easily pulled by a man or women for 2-3 hours continuously. The overall performance of the manually operated drum seeder was found satisfactory.

Fig. 2: Field performance test of drum seeder

The seed pattern characteristics were observed after germination of seeds under field condition. The average number of plants per hill was found to be 1-2. The plant growth characters like plant height and basal diameter were compared with broadcast method of sowing and depicted in “**Fig. 3**”. The jute plants were harvested at 120 DAS and retted in water for fibre extraction. The fibre yield of about 28.6 q/ha was obtained in line sowing; against yield of 22.3 q/ha in broadcast method of sowing.

Table 3: Field performance of drum seeder

Parameters	Observed values
Crop	Jute
Variety	JRO-204 (Suren)
Type of soil	Sandy loam
Size of plot	20m x 10m
Soil moisture, % (db)	22.55
Mean weight dia. of clods, mm	0.35
Speed of operation, km/h	1.6-2.0
Coverage width, m	1.0
Depth of seed placement, mm	10-15
Seed rate observed, kg/ha	2.8-3.0
Average draft, N	85.02
Power requirement, W	41.93
Effective field capacity, ha/h	0.18-2.0
Field efficiency, %	90-95
Seed distribution efficiency, %	60-70
Average number of plants/hill	1-2
Seed pattern observed	Drilling
Fibre yield, q/ha	28.6

CONCLUSION

Sowing of small seeds like jute in rows is very much desirable to save seed, to reduce the cost cultivation by cutting the cost involvement in weeding and thinning. The developed manual drum seeder for jute and other small seeded crops distributed seeds uniformly along the rows. Mechanical intercultural operations in line sown crop using cycle weeder/ nail weeder showed 60 % reduction in manual labour requirement and cost for weeding and thinning by more than 50 per cent. Due to evenly and healthy plant population, the overall yield increases fibre yield about 20-22 per cent.

ABSTRACT

A high ground clearance platform for low horse power tractor with matching weeding and spraying implements was developed. This new development will increase effective use of tractor for weeding and spraying operations in tall growing crops like maize, castor, red gram, cotton, etc. The developed platform basically consists of three components (i) Front wheel axle (ii) Rear drive wheel axle and (iii) Reworked steering set system for enhanced track width. The developed prototype of high clearance platform fitted to a mini tractor of 18.5 hp. The matching rotary weeder developed for high clearance platform is tested in castor and pigeon pea at two different speeds and two growth stages. The weeding efficiency, plant damage and fuel consumption were determined. The developed boom sprayer unit basically consists (i) Base frame to give support / fix various components (ii) Pump with manifold for flow control and pressure regulation (50 lpm & 30kg /cm² rating) (iii) Boom with height adjustable frame work and (iv) High pressure hose pipes. The standard nozzles on the boom were fitted with spacing adjustable provision to use for different types of rainfed crops. The weeding efficiency of rotary machine varied 74 to 86.8% for castor and 78.98 to 85.43% for pigeon pea, respectively at different speed and growth stage. The boom sprayer was operated in cotton crop and pigeon pea. The operator can steer the tractor comfortably and sprayer worked satisfactorily. The field capacity of the boom sprayer ranged from 0.77 to 1.15 ha/h. The newly developed implements showed significant advantage in monetary terms when compared with traditional practices.

Keywords : High clearance platform, low hp tractor; weeding; spraying..

INTRODUCTION

In Indian farming system, the weed control and intercultural operations used to be taken care of by a well set system of traditional sowing implements and matching intercultural tools combinations till recent past. But, due to introduction of new crop varieties, high yielding hybrids, farmers focus shifting more towards commercial crops. With varying crop row spaces in different soils and agro-climatic conditions, the traditional set of tools not able to meet the present days crop cultivation requirements.

Though mechanization and use of power operated equipment is picked up since last two decades, it is confined to mostly certain crops and specific operations in dryland system. For ex. in maize seeding and cobs threshing combine; in red gram sowing and grain removal using multicrop thresher. The cotton crop though present in considerable acreage in dryland system, one of the least mechanized crop in Telangana and Andhra Pradesh.

In addition to these factors, the relay cropping practice which is confined to irrigated crops like wheat in cotton [1], also slowly picking up in rainfed system due to climate variability and effectively utilizing the late rainfalls and to compensate kharif season crop loss if any occurred. The crops like gram, horse gram, cowpea are relay cropped in long duration crops red gram and cotton. Such practices enhance the overall farm income of dryland system besides generating considerable fodder biomass for livestock. The major portion of farm holders is small and marginal category in the country compounded by resource poorness in drylands. Hence, the government departments are promoting low horse power or mini tractors to decrease initial investment on power source and matching machinery. However, availability of matching implements and machinery is a problem for lower horse power tractors.

To address some of these problems, ICAR - Central Research Institute for Dryland Agriculture (CRIDA), Hyderabad has developed various matching implements such as cultivator, seed planter, Slasher etc. to name few. In spite of these efforts, utility of farm tractors are limited in dryland crop production operations like weeding and plant protection operations due to constraints in crop row configurations even in wide row spaced crops like cotton, castor and red gram. So, to increase the

utility of low horse power tractor in these operations, development of high under ground clearance and enhanced track width platform for mini tractors in the range of 18 - 22 horse power was thought off. This gives an extend service opportunity for tractors with crop based specific operational capability with matching implements and machinery. To address these problems, ICAR - CRIDA developed a prototype of high under ground clearance and track width platform for low hp tractors in the range of 18 - 22 horse power to suite to red gram and cotton crops.

MATERIAL AND METHODS

The high ground clearance platform and matching implements i.e. rotary weeder and boom sprayer for low horse power tractor were developed to address the present constraints as enumerated in instruction part of these paper, in tall growing crops like cotton, pigeon pea, maize.

Development of prototype of high under ground clearance and track width platform for mini tractors

The newly developed platform basically consists of three components (i) Front wheel axle (ii) Rear drive wheel axle and (iii) Reworked steering set system for enhanced track width **Fig. 1**. The reworked-out axle length selected such a way that, the tyres centre to centre distance was 166 cm and ground clearance 90 cm. In setting the front axle, all original features were retained while replacing axle spindle, spindle housing and steering set. The rear axle length was extended using additional step cut spindle lengths at top and lower portions. The extension spindles of rear axle were properly secured in position with the support of appropriate length bushes and pedestal bearings. The rear axle extension portions were fitted in position using a frame made of 50X5mm mild steel angle iron. The power transmission was provided from top rear drive axle to lower tyre axle using sprocket and chain system. While designing the above three basic mechanisms, all commercially available readymade parts and few reworked out components were used to reduce fabrication costs and interchange ability from one model to other model of tractor of same make within the selected horse power range. To cover the rear and side portion of the rotor shaft assembly half portion of the blades, an inverted D shape supported sheet metal structure was fabricated and fitted to the rotary weeder machine. The overall dimensions of rotary weeder are 1000 mm length, 800mm width and 120 mm height. The brief specification of high clearance platform for low horse tractor given in **Table 1**.

Table 1: Brief specification of high ground clearance platform

S No	Particulars	Specifications
1	Tractor Manufacturer	Mitsubishi Shakti
2	Make	MT 180D
3	Power, hp	18.5
4	Rear tyre track width, cm	166
5	Front tyre track width, cm	151
6	Total weight, kg	980
7	Ground clearance, cm	90
8	Turning radius, m (without brake)	5.2
9	Overall dimension, L*W*H, cm	250*199*197

Fig. 1: CAD model of high ground clearance platform for mini tractor

Fig. 2: High ground clearance platform for mini tractor

Development of a prototype of rotary weeding tool for interrow weeding

To utilize the high clearance platform effectively a rotary weeder was fabricated and attached to the power unit (Fig 3).

Fig. 3: Weeding operation in pigeon pea crop

The rotary weeder matching to high clearance platform consists of a main frame with hitch mast, gear box housing with power transmission, rotor shaft assembly with soil working tools. The rotary weeder was developed by considering the crop row geometry and machine parameters. The machine main frame consists of a 760 x 400mm rectangular shaped tubular frame made from two numbers of hollow square bars of 760mm length which are set from a 50x50x5mm M.S. angular iron welded bar. To give enough strength and rigidity to the frame 5mm wall thick and 50x50mm size tubular rectangular bar support pieces of length 30cm were welded at the centre portion of the frame. The frame thus fabricated was provided with a standard three point hitch mast. A proper seating arrangement at the middle portion of frame provided and a gear box fitted. A 35 mm output shaft that runs perpendicular to the input shaft of gear box was provided with a heavy-duty sprocket. Power to the soil working rotor blades shaft was drawn through sprocket and chain arrangement.

The rotor shaft assembly basically consists of a solid shaft, working blades, sprockets for power transmission and end bearing blocks fitted over the mounting end support brackets. The dimensions of the rotor blades and shafts were determined on the basis of speed of operation, width, depth of cut during operation and soil conditions. The overall dimensions of rotary weeder are 1000 mm length, 800mm width and 120 mm height. The L shaped blade gives better performance index as compare to other, therefore L shape blade was selected [2]. The brief specification of rotary weeder given in Table 2.

Table 2: Specification of developed rotary weeder

S No	Particulars	Specifications
1	Length x Width x Height (mm)	1000X800X120
2	Number of flanges per unit	4
3	Number of blades per flange	3
4	Total blade	12
5	Theoretical width of cut, mm	760

6	Diameter of rotor, mm	200
7	Shape of blade	L
8	Outer width of cover of rotor assembly, mm	76
9	Speed ratio (PTO to rotor shaft)	1.8
10	Safety aspects	provided

Performance parameter for rotary weeder

The performance of high clearance tractor operated rotary weeder tested in castor and pigeon pea crop. The weeder was tested for weeding efficiency, plant damage and fuel consumption at two forward speed, one blade shape and two growth stages i.e. Days After Sowing (DAS) as per standard test procedure [2], [3].

Development of a prototype of boom sprayer for high ground clearance platform

Among cotton growing farmers of the country, nearly 96% use Bollgard (BG)-II Bt in various states. India is the only Bt cotton-growing country in the world facing the problem of resistance of pink bollworm (PBW) infestation to the toxins produced by Bollgard II. The target pests becoming resistant to Bt cotton has now emerged as a new problem in parts of major cotton growing states such as Gujarat, Andhra Pradesh and Maharashtra. The available information suggests the need for proactive six-pronged insect resistance management (IRM) on Bt cotton fields. Otherwise the development of insect resistance to Bt cotton can significantly diminish the returns and benefits that are currently being derived from the technology. In fact, Integrated Pest Management (IPM) practices for Bt cotton is equally important, in which spraying equipment play a major role. Keeping this point in view, the boom sprayer matching to high clearance fitment attached tractor was developed.

The developed boom sprayer unit basically consists (i) Base frame to give support / fix various components (ii) Pump with manifold for flow control and pressure regulation (50 lpm & 30kg.cm-3 rating) (iii) boom with height adjustable frame work and (iv) high pressure hose pipes. The pump gets the required power from tractor PTO. The nozzles on the boom were fitted with spacing adjustable provision to use for different types of rainfed crops. In fabrication of the boom sprayer all the standard commercially available components were procured and reworked for tight fitments to avoid fluid leakages. The row crop sprayer was tested in the laboratory for 4-5 hours for inspection of discharge and proper working of all functional components before field trials in the cotton crop. The preliminary adjustments were made in the sprayer to avoid air lock and liquid leakage from the pipe lines. The brief specification of developed boom sprayer for high clearance tractor given **Table 3**.

Table 3: Specification of developed boom sprayer

S. No	Particulars	Specifications
1	Type of boom	Foldable
2	No. of nozzles	8
3	Nozzle spacing, mm	90, adjustable
4	Type of nozzles	Solid cone type
5	Type of pump	Piston type
6	Pump pressure, kg/cm ²	10-30
7	Type of pump drive	V-belt and pulley
8	Tank capacity, litres	150
9	Boom height, mm	Adjustable
10	Ground clearance, mm	900

Performance parameter for boom sprayer

The performance of high clearance tractor mounted boom sprayer tested in cotton and pigeon pea field (**Figs. 4, 5**). The lab testing of sprayer nozzle was conducted with nozzle discharge, nozzle spray angle, swath width at different pump pressure (**Table 4**). The actual field efficiency, theoretical field efficiency and field efficiency were calculated as per standard procedure [3].

Fig. 5: Spraying operation in pigeon pea

Table 4: Dependent and independent parameter

S. No	Independent parameter	Levels	Dependent parameter
1.	Nozzle type	1. Solid cone nozzle 2. Flat fan type	1. Discharge rate
2.	Pressure	10-30 kg/cm ²	2. Swath width
3.	Nozzle height, cm	1. 126 2. 146 3. 166	3. Spray angle

RESULT AND DISCUSSION

Performance of rotary Weeder

The developed rotary weeder was tested in castor (90cm row to row and 45cm plant to plant spacing) and pigeon pea (90cm row to row and 20cm plant to plant spacing) crops after 25 and 45 Day After Sowing (DAS). The field trials were taken up in sandy loam soil and respective crops were planted using tractor operated mechanical planter. The operator was able to steer the tractor at much ease with the new developments and no considerable plant damage observed while in operation.

The data presented in the **Table 5** shows that as the days after sowing increases, the operator has to exercise some caution (due to plant height and growth increase) to avoid plant damage. The weeding efficiency of rotary machine varied from 82.5% to 74.0 and 85.43% to 80.91 for castor and pigeon pea, respectively as speed changes from 2.0 km/h to 2.5 km/h at 25DAS. Moreover, at 45 DAS, the weeding efficiency of rotary machine decreased from 86.8 to 78.5 % and 82.56 to 78.98 % for castor and pigeon pea, respectively as operating speed changed from 2.0 to 2.5 km/h. This may be due to variation in bite length of blade due to speed. Slight variation in weeding efficiency from crop to crop may be due to moisture level variation in soil.

The plant damage during rotary weeding increased from 2.15 to 3.10% and 2.26-2.39% for castor and pigeon pea, respectively when forward speed increases from 2 to 2.5 km/h. After 45 DAS, in weeding the plant damage was varied 2.49 to 3.47% and 3.22 to 3.82% for castor and pigeon pea, respectively when forward speed increased from 2 to 2.5 km/h. It was observed that as plant height and forward speed increases damages also increases. Slight variations in plant damage may be due to difference in crop canopy spread.

Table 5: Result for rotary weeder

S. N0	Crop and growth stage	Day after sowing, DAS	Machine forward speed, kmph	Weeding efficiency, %	Plant damage, %	Fuel consumption, l/h
1	Castor	25	2.0	82.5	2.15	1.39
			2.5	74.0	3.10	1.79
		45	2.0	86.8	2.49	1.29
			2.5	78.5	3.47	1.81

2	Pigeon pea	25	2.0	85.43	2.26	1.45
			2.5	80.91	2.39	1.77
		45	2.0	82.56	3.22	1.40
			2.5	78.98	3.82	1.60

The Fuel consumption during rotary weeding increased from 1.39 to 1.79 l/h and 1.29-1.81 l/h for castor after 25 and 45 DAS, respectively when forward speed increases from 2 to 2.5 km/h. In case of pigeon pea, after 25 DAS and 45 DAS, the fuel consumption was varied 1.45 to 1.77 l/h and 1.40 to 1.60 l/h when forward speed increases from 2 to 2.5 km/h respectively. From result, it was observed that as forward speed increases fuel consumption also increases. The variation in fuel consumption with respect to other parameter may be due to difference in soil type and soil moisture status.

Performance of boom sprayer

The boom sprayer mounted on high clearance platform fitted tractor was evaluated under laboratory and field conditions in tall growing crops. Two types of nozzles i.e. solid cone and flat fan nozzles were tested to determine the discharge rate, swath width and spray angle at different combinations of nozzles height and pressure. The observations were presented in **Table 6, 7 and 8**, respectively.

From the **Table 6**, it was observed that solid cone nozzle gave slightly more discharge rate as compare to flat fan nozzle. However, use of nozzle type depends on type chemical to be used and pest to be controlled. It was also observed that as the pressure increases discharge rate also increases. The discharge rate for solid cone nozzle varied from 0.350-0.510 l/min, whereas for flat cone it varies from 0.360 to 0.486 l/min as the pressure changes from 2.5 to 3.5 kg/cm². The similar trends were also observed for flat cone nozzle as in [4].

Table 6: Discharge rate at various pressures

Nozzle type	Pressure, kg/cm ²	Discharge rate, l/min
Solid cone	2.5	0.350
	3.0	0.389
	3.5	0.510
Flat fan	2.5	0.360
	3.0	0.381
	3.5	0.486

The swath width at different pump pressures and height of nozzle was given in **Table 7**. As inferred from the data, the flat fan type nozzle gives better swath width when compare to solid cone nozzle.

Table 7: Swath width (mm) at different pressure and height of nozzle

Nozzle type	Pump pressure, kg/cm ²	Height of nozzle, mm		
		350	450	550
Swath width (mm)				
Solid cone	2.5	210	280	340
	3.0	265	340	420
	3.5	350	460	540
Flat fan	2.5	315	400	470
	3.0	360	450	540
	3.5	410	530	630

The nozzle spray angle data indicates that as pressure increases spray angle increases (**Table 8**). When pressure varied from 2.5 to 3.5, the spray angle changes from 34-53 degree for solid cone nozzle and the same is varied from 47-61 degree in case of flat fan nozzle.

**Table 8:** Nozzle spray angle at various pressure

Nozzle type	Pressure, kg/cm ²	Average Spray angle
Solid cone nozzle	2.5	34
	3.0	42
	3.5	53
Flat fan nozzle	2.5	47
	3.0	53
	3.5	61

The developed boom sprayer was tested in pigeon pea and cotton crop at forwarding speeds of 1.5, 2.0 and 2.5 km/h. The average theoretical field capacity of 0.9, 1.2 and 1.5 ha/h were observed at forwarding speeds of 1.5, 2.0 and 2.5 km/h, respectively. The corresponding average effective field capacity of 0.77, 0.97 and 1.15 ha/h was observed for respective forward speed. Whereas the field efficiency of 0.84, 0.80 and 0.76% for pigeon pea was observed. Almost similar field capacity was observed for cotton crop. Most of the time lost in tank filling due to small capacity. The good coverage was observed at 2 km/h with solid cone nozzle. The operator is able to steer the tractor comfortably and sprayer worked satisfactorily. The cost of spraying operation worked out is Rs 600/-per ha.

CONCLUSIONS

1. A high ground clearance platform for low horse power tractor was observed to be perfect solution for intercultural operation in tall growing crop.
2. Developed high clearance boom sprayer avoid direct contact of operator with chemical which reduces the health risk.
3. Multi utility platform helps to reduce cost of cultivation and drudgery involved in various operation.
4. The maximum weeding efficiency of 82.5% and 85.43% was observed for castor and pigeon pea at 2 km/h forward speed.
5. The average effective field capacity of 0.77, 0.97 and 1.15 ha/h was observed at forward speed of 1.5, 2 and 2.5 km/h, respectively for boom sprayer.
6. It can be concluded that the recommended quantity of spray liquid can be sprayed by adjusting forward speed and pressure setting.

ABSTRACT

Agriculture is done in every country from ages. Agriculture is the science and art of cultivating plants. Agriculture was the key development in the rise of sedentary human civilization. Agriculture is done manually from ages. As the world is trending into new technologies and implementations it is a necessary goal to trend up with agriculture also. IOT plays a very important role in smart agriculture. IOT sensors are capable of providing information about agriculture fields. we have proposed an IOT and smart agriculture system using automation. This IOT based Agriculture monitoring system makes use of wireless sensor networks that collects data from different sensors deployed at various nodes and sends it through the wireless protocol. This smart agriculture using IOT system is powered by Arduino, it consists of Temperature sensor, Moisture sensor, water level sensor, DC motor and GPRS module. When the IOT based agriculture monitoring system starts it checks the water level, humidity and moisture level. It sends SMS alert on the phone about the levels. Sensors sense the level of water if it goes down, it automatically starts the water pump. If the temperature goes above the level, fan starts. This all is displayed on the LCD display module. This all is also seen in IOT where it shows information of Humidity, Moisture and water level with date and time, based on per minute. Temperature can be set on a particular level, it is based on the type crops cultivated. If we want to close the water forcefully on IOT there is button given from where water pump can be forcefully stopped.

Keywords : Arduino, Temperature sensor, Moisture sensor, water level sensor, GPRS module, Humidity.

INTRODUCTION

Agriculture uses 85% of available freshwater resources worldwide, and this percentage will continue to be dominant in water consumption because of population growth and increased food demand. There is an urgent need to create strategies based on science and technology for sustainable use of water, including technical, agronomic, managerial, and institutional improvements. There are many systems to achieve water savings in various crops, from basic ones to more technologically advanced ones. For instance, in one system plant water status was monitored and irrigation scheduled based on canopy temperature distribution of the systems can also be automated through information on volumetric water content of soil, using dielectric moisture sensors to control actuators and save water, instead of a predetermined irrigation schedule at a particular time of the day and with a specific duration. Through a timed temperature threshold, automatic irrigation was triggered once canopy temperatures exceeded the threshold for certain time accumulated per day. Automatic irrigation scheduling consistently has shown to be valuable in optimizing cotton yields and water use efficiency with respect to manual irrigation based on direct soil water measurements.

LITERATURE REVIEW

As of today, some 1.1 billion planetary inhabitants do not have access to clean drinking water, and 2.6 billion do not have sanitation services. Agriculture is by far the leading user of freshwater worldwide, accounting for almost 85% of global consumption. Because of growing demand, we will need to raise food production by nearly 50% in the next 50 years to maintain our present per capita supply, assuming that the productivity of existing farmland does not decline. The latter portion of this chapter discusses ways in which this emerging crisis may be mitigated [1]. Evapotranspiration based irrigation controllers, also known as ET controllers, use ET information or estimation to schedule irrigation. Previous research has shown that ET controllers could reduce irrigation as much as 42% when compared to a time-based irrigation schedule. The objective of this study was to determine the capability of three brands of ET based irrigation controllers to schedule irrigation compared to a theoretically derived soil water balance model based on the Irrigation Association Smart Water Application Technologies (SWAT) protocol to determine the effectiveness of irrigation scheduling. Five treatments were established, T1–T5, replicated four times for a total of twenty field plots in a completely randomized block design. The irrigation treatments were as follows: T1, Weather matic SL1600 with SLW15 weather monitor; T2, Toro Intelli-sense; T3, ET water Smart Controller 100; T4, a time-based treatment determined by local recommendations; and T5, a reduced time-based treatment 60% of T4. All treatments utilized rain sensors

set at a 6 mm threshold [2]. A prototype system was developed and constructed for automating the measurement and recording of canopy, soil, and air temperature, and soil moisture status in cropped fields. The system consists of a microcontroller-based circuit with solid-state components for handling clock/calendar, sensor power, and data storage and retrieval functions. Sensors, including an analog soil moisture sensor, analog and digital temperature sensors, and a digital infrared thermometer, are widely available and inexpensive [3]. Systems were built and tested during the 2009 growing season in a corn field to evaluate performance and suitability under local conditions. The sensors performed according to manufacturers' specifications, with accuracies of ± 0.4 °C, ± 1.4 °C, and ± 0.3 °C for air-, soil-, and canopy-temperature measurements, respectively. Soil moisture sensors were calibrated and provided measurements within ± 2 kPa of the manufacturer's values. Reliability of data collection and storage averaged 91%, with most bad or missing data occurring during periods of inclement weather and electrostatic interference [4]. Efficient automated irrigation systems, which can irrigate the substrate of potted plants to a desired level and supply those plants with just the amount of water required for normal plant growth are currently not available [5]. These systems, if developed, could reduce wastage of irrigation water due to excess application. This subsequently could reduce leaching and run-off, and aid growers to cope with increasing regulations of water-use by state governments in the US. Here we describe an irrigation controller that irrigates a substrate to a set-point (volumetric water content, θ) and maintains θ close to that set-point for several weeks. The controller uses calibrated, dielectric moisture sensors, interfaced with a data logger and solenoid valves, to measure the θ of the substrate every 20 min. [6].

SYSTEM ANALYSIS

India's major source of income is from agriculture zone and 70% of farmers and general people depend on the agriculture. So the agricultural system in India should be advanced to reduce the manual efforts of farmers. Various operations are performed in the agriculture field like seed sowing, weeding, cutting, pesticide spraying etc by the farmers manually. In India most of the seed sowing process are operated manually. These manual technique are replaced with automated techniques. The fabrication of ground nut sowing machine is reasonable and low cost effective for agricultural production. The basic requirements for small scale cropping machines are, they should be suitable for small farms, simple in design and technology and versatile for use in different farm operations. IOT plays a very important role in smart agriculture. IOT sensors are capable of providing information about agriculture fields. We have proposed an IOT and smart agriculture system using automation. This smart agriculture using IOT system is powered by Arduino, it consists of Temperature sensor, Moisture sensor, water level sensor, DC motor and GPRS module. When the IOT based agriculture monitoring system starts it checks the water level, humidity and moisture level.

BLOCK DIAGRAM

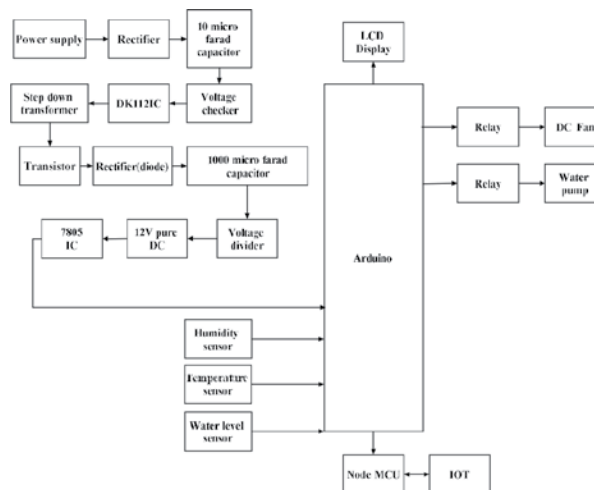

Fig. 1: Block diagram of IoT based smart agriculture monitoring system

Fig. 1 shows the block diagram of IOT Based Smart Agriculture Monitoring System. This IOT based Agriculture monitoring system makes use of wireless sensor networks that collects data from different sensors deployed at various nodes and sends it through the wireless protocol. A robot is a mechanical, artificial agent and is usually an electromechanical system, because of software programming it makes complicated tasks easy to perform. Applying automation to agriculture its advancements to

the industry while helping farmers to save money and time. In this system automatic seed sowing is done which aims to drop seeds at particular position with specified distance between two seeds and lines while sowing by using PIC Microcontroller. This smart agriculture using IOT system is powered by Arduino, it consists of Temperature sensor, Moisture sensor, water level sensor and DC motor. Our project model includes wheel, Rod, Digging rod. Solenoid Valve is used as Seed Feeder, where we have to keep the seeds. It is closed by default. While the system activates, the solenoid value does opens and closes based on the programmatic time. Seed falls in to the land. It sends SMS alert on the phone about the levels. Sensors sense the level of water if it goes down, it automatically starts the water pump. If the temperature goes above the level, fan starts. The main focus of this system is its Automatic way of sowing the seeds. The seeds are been sowed in a proper sequence which results in proper germination of seeds. This automatic way of sowing seeds using a robot reduces the labor requirement. Here the wastage of seeds is also been reduced to a greater extent. This system has been developed for the sowing of seeds in an automatic way. Here with the help of a robot the seeds are been dispensed in the soil in a proper sequence hereby reducing the wastage of seeds.

HARDWARE REQUIREMENT

Power Supply

A power supply is an electronic device that supplies electric energy to an electrical load. The primary function of a power supply is to convert one form of electrical energy to another and, as a result, power supplies are sometimes referred to as electric power converters. Some power supplies are discrete, stand-alone devices, whereas others are built into larger devices along with their loads.

SMPS

SMPS transfers electric power from a source (AC mains) to the load by converting the characteristics of current and voltage. SMPS always provide a well regulated power to the load irrespective of the input variations. SMPS incorporates a Pass transistor that switches very fast typically at 50Hz and 1 MHz between the on and off states to minimize the energy waste. SMPS regulates the output power by varying the on to off time using minimum voltage so that efficiency is very high compared to the linear power supply.

Input rectifier

The AC input from mains is first rectified in the SMPS using a rectifier to convert it into DC. The rectifier consisting of a full wave diode bridge or module that produces an unregulated DC voltage to the Smoothing capacitor. The input AC passing into the rectifier has AC voltage pulses that may reduce the power factor. So control techniques are used to force the average input current to follow the sine wave.

Inverter

This stage converts the rectified DC into AC using a power oscillator. The power oscillator has a small output transformer with a few windings at the frequency 20-100 kHz. Switching is controlled by a MOSFET amplifier. The output AC voltage is usually isolated optically from the input AC by using an Optocoupler IC for safety reasons.

Voltage regulator IC 7805

7805 is a voltage regulator integrated circuit. It is a member of 78xx series of fixed linear voltage regulator ICs. The voltage source in a circuit may have fluctuations and would not give the fixed voltage output. The voltage regulator IC maintains the output voltage at a constant value as shown in **Fig. 2**.

Fig. 2: Voltage Regulator IC 7805

PIC Microcontroller 16F877A

The PIC microcontroller PIC16f877a as shown in **Fig.3** is one of the most renowned microcontrollers in the industry. This controller is very convenient to use, the coding or programming of this controller is also easier. One of the main advantages is that it can be write-erase as many times as possible because it use FLASH memory technology. It has a total number of 40 pins and there are 33 pins for input and output. PIC16F877A is used in many pic microcontroller projects. PIC16F877A also have many application in digital electronics circuits.

Fig. 3: PIC 16F877A Microcontroller

Sensors

Temperature sensor is a device, to measure the temperature through an electrical signal it requires a thermocouple or RTD (Resistance Temperature Detectors). If the difference in voltage is amplified, the analogue signal is generated by the device and it is directly proportional to the temperature. The coolant temperature sensor, also known as the coolant temperature switch, is an engine management

System sensor that is used to monitor the temperature of the engine's coolant. Most coolant temperature sensors operate using electrical resistance to measure the temperature of the coolant.

A humidity sensor as shown in **Fig. 4** (or hygrometer) senses, measures and reports both moisture and air temperature. The ratio of moisture in the air to the highest amount of moisture at a particular air temperature is called relative humidity. Relative humidity becomes an important factor when looking for comfort.

Fig. 4 : Humidity sensor

therefore, while selecting a strong and consistent one, one should think about the requirement.

LCD display

LCD (Liquid Crystal Display) screen as shown in **Fig. 5** is an electronic display module and find a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. These modules are preferred over seven segment LEDs. The reasons being: LCDs are economical; easily programmable; have no limitation of displaying special & even custom characters (unlike in seven segments).

ARDUINO

Arduino as an open source hardware and software company, project and user community that designs and manufactures single board and microcontroller kits for building digital devices and interactive objects that can sense and control both physically and digitally. Its products are licensed under the GNU Lesser General Public License (LGPL) or the GNU General Public License (GPL), permitting the manufacture of Arduino boards.

SOFTWARE REQUIREMENT

Proteus Software

Proteus is software for microprocessor simulation, schematic capture, and printed circuit board (PCB) design. It is developed by Lab center Electronics. The XGame Station Micro Edition was designed using Lab center's Proteus schematic entry and PCB layout tools.

Embedded C

Embedded C is a set of language extensions for the C Programming language by the C Standards committee to address commonality issues that exist between C extensions for different embedded systems. Historically, embedded C programming requires nonstandard extensions to the C language in order to support exotic features such as fixed point arithmetic, multiple distinct memory banks, and basic I/O operations. In 2008, the C Standards Committee extended the C language to address these issues by providing a common standard for all implementations to adhere to. It includes a number of features not available in normal C, such as, fixed-point arithmetic, named address spaces, and basic I/O hardware addressing.

CONCLUSION

This IOT Based Smart Agriculture Monitoring System save time and reduce human effort. In most of the agriculture we need a separate person to sowing seeds. This is a long time process. In rush hours workers will be in hurry to do such workers. This system will overcome this problem.

ABSTRACT

This paper addresses a Multipurpose Harvesting Machine for lowlands which is fabricated with very simple mechanisms at a very low cost. Cutting and gathering of the crop are important agricultural operations which demand a considerable amount of labor. The availability and cost of labor during harvesting season is a problem. The shortage of labor during harvesting season and sudden variation of the weather condition causes a great loss to the farmers it is, therefore, essential to adopt the mechanical methods so that the timeliness in the whole operation could be ensured. The use of mechanical harvesting devices has been increased in recent years. To harvest crops, farmers are usually using reapers or combines. But these are very costly, thus making it unaffordable to most of the small farmers. Although, some manual operated reapers were developed. But as because of the limitations of manual power, none of them become popular among farmers as the power available for transportation of the machine as well as cutting and conveying of the crop was not sufficient. In this research, we have studied and fabricated a Multipurpose Harvesting Machine at a very low cost and techniques were carried out.

Keywords : Multipurpose harvesting machine; Crop cutter; Crank and slotted quick return mechanism; Pulley; Gears.

INTRODUCTION

India is an agricultural country. About 70% of our population depends on agriculture. One-third of our national economy comes from agriculture. Our agriculture remains underdeveloped for a long time. We did not produce enough food for our people because of the manual harvesting of crops. But things are now changing by the replacement of machines to do the necessary harvesting works. Still, lowlands are facing a major problem in handling those heavy machines. There comes the idea of manufacturing a multipurpose harvesting machine for lowland where the main aim is to reduce the weight of the machine as well as the cost so that the poor farmers of our country can afford such machines ultimately leading to higher production in less time.

METHODOLOGY

Basically, our study is mainly focused on our native state Tripura. Tripura being a hilly state, the amount of plain land is very limited. So, mostly agriculture is done in lowland areas. The property of the lowland is such that it cannot withstand the load of heavier machines (more than 100kg). So, to overcome this and eliminate labor dullness, an affordable machine of limited weight needs to be introduced. The major problem occurs during the harvesting season. So, our main approach is focused on the cutting and gathering of crops. So, for the fulfillment of our aim, we followed some steps. We had visited various agricultural lands and from there we got to know the problems faced by our farmers. What are the machines they are using, how much the existing machinery cost, whether these machines are feasible for lowlands, what are the existing traditional techniques, and the price of labor?

LITERATURE REVIEW

The model has been designed utilizing our own ideas & knowledge, but still we have taken some inspiration from the papers listed below:

Moheb (2006) designed a self-propelled machine suitable for cutting crops. The actions of this machine involve cutting, reeling, conveyor belts, and transmission systems. We used this as a guide and replaced the conveyor belt mechanism in reducing the overall weight of our machine.[1]

Yuming Guo's paper (2016) explains the relations between the stalk strength and cutting force that is require for cutting the soybean. This paper was supportive in guiding the calculations front for rice harvesting.[2]

WORKING PRINCIPLE

This machine consists of a quick return Mechanism for reciprocation of cutter blade over stationary cutter blade and this mechanism is also used to convert rotary motion into linear motion. This machine is run by 9.5HP, 6000rpm 2 stroke petrol engine. One end of the output shaft is connected to the Crank and slotted lever mechanism which converts the rotary motion of the shaft into reciprocating motion of the cutter blade. Reciprocating cutter blade slides over the fixed blade and creates scissoring action responsible for cutting the crop and another end is connected to the collecting mechanism and hence helps in gathering of crops.

CAD MODEL OF PARTS OF THE MACHINE

The drawing of the crop cutting machine will be presented by using CATIA drawing software and the pictorial views are presented below:

Fig 1: Isometric view

Fig 2: Side view

Fig 3: Top view

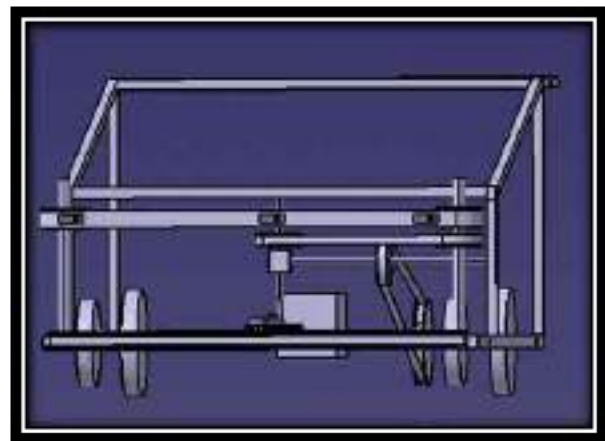

Fig 4: Front view

CONSTRUCTION

The machine mainly performs two functions 'Harvesting and collecting'. The machine consists of mainframe, petrol engine, cutter mechanism, collecting belt mechanism, bevel gear mechanism and crank slotted lever mechanisms and the details are given below:

Mainframe: - The mainframe is designed in such a manner that it must be lightweight and also able to carry the load of the petrol engine and other accessories. The machine will have dimensions of 30x50 inches as width and length.

Fig 5: Mainframe

Petrol Engine: - A two-stroke engine is used because of more power strokes and lightweight. The engine will be run by a 9.5 H. P 6000 rpm petrol engine. We choose petrol because of the small size engine.

Fig 6: A two-stroke engine

Cutter mechanism:- Cutter assembly consists of both sliding and stationary cutting blade. Along with the cutting, the collection of crops is also done from the same power source with the help of three different belt pulley attachments. The upper blade follows a quick return mechanism while the lower blade remains stationary and moves along the motion of the vehicles thus providing a scissoring action.

Fig 7: Cutter assembly

Bevel Gear Mechanism:- It is required to transmit power to two mechanisms – the quick return mechanism and the collecting mechanism by diverting the motion by 90°.

Fig 8: Bevel gear

Collecting Belt mechanism:- In this mechanism, the transmission of power takes place between the parallel shafts. Consists of two pulleys over which an endless belt is passed encircling both and Rotary motion is transmitted from driving pulley to driven pulley.

Fig 9: Collecting Belt mechanism

Crank and slotted lever quick return mechanism:- This is the mechanism basically used in shaping machines, where the rotational motion of the crank will be converted to the linear mechanism of the slider.

Fig 10: Crank and slotted lever mechanism

MATERIAL USED

Various materials are used for various components of the harvesting machine which are given below:

- i. Carbon steel is used for Bevel gear because of its high toughness and high strength.

- ii. Mild steel is used for angle because mild steel is preferred for the structural framework and bearing stresses.
- iii. Mainframe is mainly made of Iron.
- iv. Cast iron is used for pulley because of its low cost.
- v. Assynthetic rubber is flexible to bend, so it is used for V-belt.
- vi. Because of high weldability and machinability of mild steel, it is used for shafts.

DESIGN OF MACHINE

Calculation is a vital element of designing. For designing of the machine, the calculations for finding the wheel RPM & for finding the RPM of driver & driven pulley is given below:

Calculation of Wheel RPM

Diameter of the Wheel (D) = 16 inch

$$= 16 \times 25.4 = 406.4\text{mm}$$

Diameter of driver Pulley (d1) = 7 inch

$$= 7 \times 25.4 = 177.8 \text{ mm}$$

Diameter of driven Pulley (d2) = 4 inch

$$= 4 \times 25.4 = 101.6 \text{ mm}$$

Perimeter of wheel = $\pi D = \pi \times 406.4\text{mm}$

$$= 1276.54 \text{ mm}$$

Speed of vehicle = 10 km/hour

$$= 10 \times (5/18) = 2.78 \text{ m/sec} = 2777.8 \text{ mm/sec}$$

Revolution of wheel/ sec = $(2777.8/1276.54)$

$$= 2.176 \text{ Rev/sec} = 130.56\text{Rev/min}[3]$$

Calculation for driver and driven Pulleys

RPM of driver Pulley = RPM of Wheel

$$= 130.56 \text{ RPM}$$

$$(d_1/d_2) = (N_2/N_1)$$

$$N_2 = (d_2 \times N_1) / d_1 = (177.8 \times 130.56)/101.6$$

RPM of driven Pulley (N_2) = 228

Blade reciprocation in 1 revolution of driven Pulley = 2 Total blade reciprocation in 1 min. = 228×2

$$= 456$$

Total reciprocation of blade in 1 sec = $456/60$

$$= 7.6 \cong 7 [3]$$

Forces and Energy calculation required to cut the Crop:

Area of the wheat straw to cut by 1 teeth of blade

$$= 2 \times (50 \cos 60^\circ) \times 5 = 250 \text{ mm}^2$$

Area of wheat straw cut by the 7 teethes

$$= 7 \times 250 \text{ mm}^2 = 1750 \text{ mm}^2 \text{ A} = 0.00175 \text{ m}^2$$

Shear strength of the wheat straw (τ_{ult})

$$= 10 \text{ MPa} = 10 \text{ N/mm}^2$$

Required cutting force (F) = $\tau_{ult} \times A$

$$= 10 \times 1750 \text{ N} = 17500 \text{ N} = 17.5 \text{ kN} [4]$$

Calculation for the velocity of collector mechanism belt

$$\text{RPM of 2nd driven pulley} = \text{RPM of 1st driven pulley} = 228$$

COST ESTIMATION

Cost estimation is the approximate cost of the product that will be required for the manufacturing of the product. The total cost of our machine depends on the following aspects:

- i. Raw Material Cost (Includes angles, shaft, engine, wheel, sheet metal, paint, petrol)
- ii. Standard item cost (Includes nut, bolt, bevel gear, pulley & belt, bearing, grinding & cutting blades, drill bit)
- iii. Machining Cost (Includes turning, drilling, milling cost)
- iv. Transportation cost.

Item	Materials	Total cost (Rs)
Wheels	MS	500*4=2000
Engine	9000
Cutter blades	Stainless steel	4000
Pulley	400*7=2800
Body frame	Cast iron	8000
Machining cost	3000
Other accessories including transportation cost	3200

Total Cost: Rs 32000

WEIGHT ESTIMATION

In the lowland area, the maximum weight that can allow running the harvesting machine is 100 kg. If the weight goes beyond that limit, then it will be difficult to operate the machine. So, we try to estimate the approximate weight of the machine:

Parts name	Weight
Mainframe	35kg
Engine	8kg
Pulley	6kg
Belt	5kg
Cutter	4kg
Wheel	20kg
Accessories	6kg

Total Weight: 84 kg

ADVANTAGES

The multipurpose harvesting machine is mainly designed to uplift the farming section of our country. This machine plays a vital role in agriculture and some of its advantages are given below:

- i. Reduce the human effort- Crop harvester is mainly designed to reduce the human effort in which only one operator can

handle the machine.

- ii. Reduce the cost- In agriculture for cropping and ploughing, it can do work at the cheapest prices because it saves the worker cost.
- iii. Reduce the time- By using this machine, they increase the capacity of the working and cutting and it can possible the maximum cutting within minimum time.
- iv. Easy to handle- This machine is easy to handle and we can easily start the machine.
- v. Efficient in crop cutting- Adjustable blades are arranged at ground level leaving minimum residues and hence it will help to reduce the pollution due to the burning of residues mainly in northern India.

RESULTS AND DISCUSSION

Since the main concentration of our design is to reduce the weight as well the cost keeping in mind the standard of mechanism, so the comparison between cutting time of 1 Kani land by machine & by labor is as follows:

FOR MACHINE

- i. The machine is working in 1 Kani (1600 sq. feet) area = the fuel consumption is 1.5 liters/hour.
- ii. Total cost = Fuel cost (Rs. 150) + labor cost (Rs. 350)+ M/C cost (Rs. 50) = Rs.550
- iii. Time for cutting of 1 Kani area = 2 hours.

FOR LABOR

- i. Cutting time for 5 labor in 1 Kani area of farm = 6 hours.
- ii. Labor Working in 1 Kani area the associated cost = Rs. 350/head
- iii. Total cost = Rs. 350*5 =Rs. 1750

So, from above we can see that the harvesting time of 1Kani land takes 6 hours for labor & 2 hours for the machine. Our model is $(6 - 2) * 100/6 = 66.67\%$ better than the traditional model in saving time and $(1750 - 550) * 100/1750 = 68.57\%$ better in saving money. Hence in the above comparison, it is clear that the cost of working by machine in the farm for said application is less as compared to labor cost. Further we are using a single power source for both scissoring action as well as for motion of wheels and hence we can eliminate the motor as used in some existing machines. Also, we are using removable cutters and can increase the number of cutters if needed. So, our design is more efficient as compared to manual processes.

CONCLUSION

The main concentration of our design is to reduce the weight as well the cost keeping in mind the standard of mechanism. For the development of this harvesting machine, we are utilizing all the past techniques and concepts. We also tried to create a simple mechanism for this machine so that everyone can handle it easily. Our model is 66.67% better than the traditional model in saving time and 68.57% better in saving money. We have reduced the weight to almost half compared to existing machines. Thus, we can conclude that by using this machine in lowland areas and other agricultural lands, we can increase the production rate. The market share will also increase, contributing more to the economy of our country.

Architectural Engineering

Fractal Geometry as an Adaptive Technique for Human Capital Development: A Review based on Indian Temple Architecture

Shynu R V

*Department of architecture, APJ Abdul Kalam Technological University,
TKM College of Engineering, Kollam*

✉ *shynurobert@gmail.com*

ABSTRACT

Architecture design configuration is an incredible and powerful medium that enhance performance over society. The conduct and capital development of humankind rely on the sort of environment which they perceive. This writing survey endeavours to research fractal-based social practice through the instance of the ancient Indian temple built environment. Sensible assessment pack investigating the concept of built environment in sanctuary design. Additionally, specialists have been investigating the realities with respect to the impact of geometrical patterns over sanctuary design. Sanctuary configuration is a mechanism of communication, and critical to recognize its importance in the social system, since fractal designs align with visual attention and structural efficiency. Indian sanctuary designs have a basic part in attention engagement and cognition, it is appropriate to find the centrality of social impact that dependent due to the manufactured temple environment. Ancient social data was polished as Vedas in which patterns has a basic work. Pros have been exploring the real factors concerning the effect of numerical models over the constructed environment of sanctuary buildings. Temple design development dependent on numerical calculations and discoveries show that the customary culture has a significant part to direct Fibonacci gathering for legitimate practice. The cognition of human over such fractal-based visual data must be confirmed experimentally for additional understandings in the domain of human capital development.

Keywords : Communication; Fractal; Social system; Environment; Cognition.

INTRODUCTION

The design principle is a crucial element in the theory of architecture. An efficient design can deliver information for communication and visual information is considered as an element of communication in the architectural design. The formation of a social system depends upon the communication medium. So built environment as a medium reflects the communication quality of the social system. Each social system depends upon the communication system. Society is only possible where communication is possible [1]. Luhman the German sociologist and a prominent thinker in system theory state that communication can be considered as the basic unit of observation for the assessment of the operation of the social system. The limit of modern society is the limit of communication [2]. Individuals do not participate in society unless they engage in communication [3]. Luhman states that social system uses communication as their particular mode of autopoietic reproduction. Autopoietic systems are a system that reproduces themselves from within the system. This statement refers that such system based practices improves the productivity and performance. This autopoietic system represents as fractal geometry because of fractal exhibit self-similarity [4]. Luhman considered media as a vehicle to communicate. Similarly architectural built environment is a medium of the vehicle to communicate for its user. The vehicle increase the reachability of addresses and the probability that addresses will receive information 'but they do not guarantee the success of the information' [5]. These data demonstrate the probability of delivering information more effectively based on fractal pattern through the built environment.

BACKGROUND STUDY

Initial investigations will focus on the fractal patterns. The concept of clarifications regarding the examples in nature and investigating the Fibonacci arrangement to comprehend its effectiveness [6]. The examination shows human visual information process capacity restricted to enormous amount of data, so conventional practices as temple architecture addressed such data perception through three-dimensional environments for faster information processing [7]. Patterns displayed on the built environment of temple design. Exceptional bona fide records open on old temple form practices, the assessment acknowledged that temple structure responded reliant on the exacting show [8]. Indian temple form development has a fantastic customary history of the practice. The investigation expected that the Harappan human advancement related to the Vedic period and shows

that the Vedic period has begun before 2000 B.C [9]. This information shows the period of customary assembled practice. Vastu is an assessment structure which has used in Indian built practice [10]. Studies show that during antiquated time creators chronicle a decent manufactured structure, with the guide of plan and height through the use of Vastupurusamandala is thought of [11]. Collectors perceived that a bit of the Vedas works formed during the fifteenth to fifth century B.C. From the seventh and eighth century, A.D. Chalukya line disengaged into two general classes, the Nagara style and the Dravida style. The study clearly shows the point by point change information on the manufactured type of both Nagara and Dravida sanctuary engineering [12]. Likewise, the geometry dependent on Vastupurushamandala clarified the evolutionary advancement of Nagara style and Dravidian style [13]. These styles are the most refined cases which show the social characteristics to the extent Golden proportion and Fibonacci sequence over the temple built environment [10].

METHODOLOGY

The literature review contains a thematic investigation to find subjects inside the data. A snowball analysing approach used to recognize relevant wellsprings of information. Individuals who may move toward disseminated or unpublished work concerning Fibonacci groupings in social practice also considered. It was sensible to discover this data through both formal and easy-going courses. Also, a couple of investigation specialists had reached to discover this data. Finally, institutions and schools having data concerning open educational documentation are added to the review furthermore. The information were then ordered into different sorts as per arrangement rules as appeared in **Table 1**. The papers were then isolated by the subjects. A specific code had created for reference. For many years it has seen an extending examination of composting volume focused in on the capacity of fractal in designing and visual perception. Overall assessment dispersions from various countries show worldwide enquiry reliant on the fractal. Regardless, the assessment data isn't explaining the fractal models' prompt relationship with the built environment because of temple design and its association with social practices.

Table 1: Classificatory category and definitional criteria

Category	Definitional criteria
Group 1	Clear fractal centre. Solid proof, clear outcome
Group 2	Fractal related. Solid proof, clear outcome
Group 3	Clear Vedic culture centre. Some proof
Group 4	Not limited to Vedic culture. Some proof
Group 5	Clear structural core interest
Group 6	Not limited to measurable data
Group 7	Published reports
Group 8	Unpublished reports
Group 9	Institutional documents

ANALYSIS

The disclosures emerge from the composition on Fractal progressions can be summed up under a couple of headings.

Fractal and Temple Architecture

The property of self-similarity recursive geometry insinuated Fractal pattern. Obsolete Indian mathematicians are capable at the count. They applied their knowledge into math in the different terrain also. They saw and grasped the principles of emphasis, accentuation and self-similarity from trees, water and ground cover that keep the fractal norms. Temple design painstakingly adhered to the Vastu norms, which depict self-similarity of its number related class. The temple rise influences the fractal design, by controlling a two-dimensional structure plan to the course of action by three-dimensional portrayal. **Fig. 1** illustrates the sample of fractal based built form in south India. The investigation recognized that visitors and voyager's thought influenced by these self-similarity parts [14].

The investigation evaluated to understand sanctuary designing arrangement guidelines over the count of the early Nagaracella (especially in the curvilinear Shikhara of the northern Indian Nagara culture). Consistently lessening groupings of self-similarity structures recognized outwardly of the superstructure [15]. These explain the presence of fractal-based practice in Indian show all throughout the north and south zones. Basically, fractal features are recognized on KandariyaMahadev temple at

Khajuraho as fractal count [16]. This information points out that the outdated Hindu religion has a strong numerical perspective over their collected characteristic practices. The examination addresses self-similarity that progresses the fractal speculation through Indian sanctuary configuration practice [14]. Therefore, a reasonable affiliation chose in fractal and social symbolism. As demonstrated by Indian masters of Vedic period they don't authentically reflect the character of nature in their speciality anyway make comparing with nature [17]. This preparation is on the grounds that ordinary people have not progressed to follow such an astounding character of nature around them, so they duplicate simply its property.

Fig. 1: Brihadisvara Temple, Thanjavur, Tamil Nadu

Fractal and Nature

History perceived that the central content in the out of date library is the Vedas since it is the important Indian Heritage. To the information, this heritage primarily perceived as the basic human advancement that is the Vedic Aryan turn of events. Vedic data particularly followed reliant on the points of view towards nature and life. Additionally, Aryans were known as the posterity of nature, since they are thinking about nature minutely [18]. That is the Vedic period may have been the utilization of nature guidelines subject to human-based preliminary or discernment revelations. Since the sanctuary design practices are painstakingly kept subject to the Vastu norms and show the self-similarity character over its natural arranging and keep the developed standards reliant on human degrees. The examination by Dutta and Adane in 2014 shows the evidence of replication in self-similarity, various accentuations, components and unusualness. The different scales are the ones that express the crudeness of Hindu sanctuary fractal designs. The best occasion of the model is the Shikhara of Khajuraho sanctuary design were the repetition of apexes notice explicit degrees and rules similarly as numerical properties [19]. Advanced reproduction strategy is utilized for structures to portray antiquated temple engineering for understanding its shape grammar, and its correlation with manufactured structures from the coding point of view [20]. All these examination examinations propose the conceivable outcomes that sanctuary configuration utilized dependent on parametric structure generative standards. A study led with 3D scanned models with the guide of computational CAD-based environment to clarify few parameters [21]. Again these revelations express the effect of the fractal design over the manufactured structure, since fractal mirror the properties of nature.

Fractal and Built Environment

The examination recognized that the Golden proportions and Fibonacci numbers were utilized in the design development for aesthetical just as utilitarian purposes. The sequential Fibonacci numbers or arrangement has numerical ideas which lead to the Golden proportion. Studies show Egyptians utilized the Golden proportion for the development of pyramids [22]. At the point when we notice nature can recognize the Fibonacci number. The example of the petals on blossoms, a course of action of leaves in the stem of a plant, the pineapples scales shows the presence of Fibonacci number. Also, the examination led by Omotehinwa and Ramon in 2013 demonstrates that Fibonacci groupings are sorted out in the human body parts. Additionally, it is distinguished that numerous human body parts have been proportioned by the brilliant proportion [23][24]. Since architectural practices are concern with human scale, it is pertinent to adhere to these design standard to chronicle subjective spaces. Akhtaruzzaman and Shafie in 2011 express that Golden Proportion cadence is additionally figured in the human pulses [26] likewise it is distinguished that Penrose tiling have numerous regular highlights identified with the pentagon and consequently to the Golden Ratio [25]. Since Penrose is associated with fractal and Fibonacci numbers, this data will prompt further enquiry in researching the productivity of the Golden proportion as a design arrangement. All these information demonstrate connote

the connection among fractal and configuration impact over various domains. According to the mathematical explanation, the Fibonacci square shape can be imagined as the course of action of square shapes in which the sides are two reformist Fibonacci numbers long. This clarifies that it is made through squares with sides having Fibonacci progression. Moreover, it is known as a Golden square shape when a square shape's sides are identical to the Golden extent [27]. It additionally distinguished that the Golden Ratio is outwardly satisfying and restricted to feel as well as nature and human body extents [25]. This mirrors the affiliation and association among nature and human wisdom in the space of the Fibonacci progression. Also, the twisting has a type of an example on nature that is known for its self-similarity that creates or fills fit as a fiddle without changing its profile. The shell of snails and the shell shows comparable winding shapes. This implies the presence of fractal designs in nature. One can outwardly follow them easily as a result of the satisfying character of the twisting shape because of the presence of these fractals. All these data reflects the efficiency of a fractal based profile on its form for productivity and performance. Essentially, **Fig. 2** speak to fractal-put together Indian social practice concerning the socially constructed environment. This training exhibits fractal calculation adjusted to its social framework because of its natural characteristics.

Fig. 2: The Royal Palace, Thanjavur, Tamil Nadu

CONCLUSION

This research might be an underlying examination concerning the Fibonacci course of action dependent on old social practice and its effect on the built environment for human resources improvement. Through a wide composing overview and examination of existing subjects reveals fractal-based regular practice and made constructed association. The effect of Fibonacci over the built environment of sanctuary design through abstract publication concerning ordinary practices so far recognized. This investigation is inciting the route for exploring the character of fractal nature-based Indian custom and its foundation of data, which has a colossal effect over visual communication based practices. Investigation maintains that the fractal estimation progresses more record in settling on a choice about the wonderfulness than visual complexity [28]. This result suggests fractal properties sway in visual acknowledgement that must moreover analyse to appreciate fractal-based arrangement practices over the amassed environment for choosing successful characteristic communication. Basically, the examination discusses the visual elegant acumen by virtue of the fractal-based arrangement in the streetscape. The created information will have the option to comprehend whether fractal math can proceed as a vehicle of the design for compelling communication as a versatile procedure for human capital development. While coordinating the information in the field of design investigation, these outcomes may be giving the diagnostic assertion about how an individual gets and comprehends data for social execution. Indian sanctuary engineering utilized fractal on its built form, it is anticipated that such pattern language upgrades the view of the user for social

execution. Since fractal designs are incorporated over sanctuary structure for its auxiliary proficiency just as data liberation. The sanctuary structure itself is a three-dimensional historical data representation through its surface for human capital development on a social system. The study anticipated that solitary solace environment can ensure the compelling communication on the part of human perception. So further research examinations must be utilized for seeing how effective environment can be worked for better data trade for human capital development.

ABSTRACT

2BHK Dignity Housing Programme is a unique initiative of Government of Telangana for constructing Double Bedroom houses for shelter less poor people below Poverty line (BPL) with an objective of achieving Slum-free cities. The Programme aims to provide Double Bedroom houses free of cost to the beneficiaries and avoids them from getting into debt trap. The programme intends to provide dwelling unit (DU) with plinth area of about 52 sq.m. with two bedrooms, hall, kitchen and two bath-cum-toilets. Civic infrastructure such as Cement Concrete roads, Storm Water Drains, Underground Drainage System, Protected Water Supply, Electrification Works and Socio Infrastructure such as Primary Health Centers, Community Centres, Schools, Bus Stands, Parks, Play Grounds, Tot-lots etc., are provided. Vertical construction strategy is adopted to accommodate more beneficiaries as the available land is minimal. Planning of these structures was done carefully keeping balance between safety and economy. Promotion of State of Art technologies like Shear wall technology and Pre-cast technology to complete the Project in a short time with higher precision and reduction of labour compared to conventional practise.

Keywords : Dignity Housing; Beneficiary; Technologies; Infrastructure; Self-Reliant Society.

INTRODUCTION

Pradhan Mantri Awas Yojana (PMAY) Mission launched on 25th June 2015 intends to provide Housing For All (HFA) by the year 2022. The Government of Telangana have formulated the Double Bed Room Housing Scheme in the month of October 2015 with an objective to provide dignity to the poor. There is no beneficiary contribution under this scheme, which is one of its kind. In rural areas, beneficiaries solely depend on seasonal conditions for their earnings, the 2BHK housing helped in protecting them from debt traps.

Greater Hyderabad Municipal Corporation (GHMC), an Urban Local Body notified in 2007 is spread over 625 sq.km having a population of 6.81 million (Census 2011) is divided into 6 zones and 30 circles. The Government of Telangana has given One-lakh 2BHK Housing units as target for GHMC in the first phase.

The 2BHK Housing Scheme in Urban areas is dovetailed with PMAY (Urban) under Affordable Housing in Partnership (AHP) vertical, wherein the Mission provides Central Assistance to the implementing agencies through States/Union Territories (UTs) and Central Nodal Agencies (CNAs) for providing houses to all eligible families/ beneficiaries. The Central Sanctioning and Monitoring Committee (CSMC) of Government of India (GOI) has accorded sanction for these houses in their 4th, 6th, 26th and 51st CSMC Meetings.

As per PMAY (Urban) guidelines, the size of a house for Economically Weaker Section (EWS) could be up to 30 sq. mt. carpet area, however States/UTs have the flexibility to enhance the size of houses in consultation and approval of the Ministry. 2BHK Programme of the Government of Telangana intends to provide dwelling unit with plinth area of about 52 sq.m comprising two bedrooms, hall, kitchen and two bath-cum-toilets.

The GHMC adopted two-pronged strategy to achieve the target. One is the development of in-situ slums and the other is construction of Housing Projects in vacant lands. All the layouts under the Project are approved by Town and Country Planning Department and a Single window cell formed for this purpose with official from Hyderabad Metropolitan Development Authority (HMDA), Revenue, Aviation and Fire Departments. Based on the availability of sites, the houses are being taken up in Cellar+Stilt+9, Stilt+5 and G+3 Floors with a unit cost of Rs.8.65 Lakhs, Rs.8.50 Lakhs and Rs.7.75 Lakhs respectively for housing and infrastructure. Lifts and Generators are provided in Cellar+ Stilt+9, Stilt+5 floor structures. Fire fighting arrangements are covered for Cellar +Stilt+9, Stilt+ Stilt+9 floor structures.

The Construction of One Lakh Houses under 2BHK Housing Programme is taken up with a Project Cost of Rs.8598.58 Crores. GOI provides Central Assistance for an amount of Rs. 1.50 Lakhs per DU under PMAY which contributes to around 18% of the Project Cost. The balance 82% of the Project Cost is being borne by the Govt. of Telangana.

DEMAND SURVEY

Area specific demand assessment is carried out in the GHMC duly consulting the stake holders/ slum dwellers/ beneficiaries.

Necessary Demand Survey for 2BHK housing in GHMC limits has been conducted as part of the State Government's Samagra Kutumba Survey (Comprehensive Household Survey) in the year 2014. Based on parameters like Own Thatched Shelter, Rent-Thatched Shelter, Rent-Tiled Shelter, Temporary Thatched Shelter & Temporary Tiled shelter etc., it was estimated that there is a demand for 4.57 lakh families with housing requirement in GHMC limits.

Demand Validation is being done by Regional Centre for Urban and Environmental Studies (RCUES), Hyderabad and the beneficiary data is uploaded in PMAY Website.

LAND POOLING- TSUNAMI CONVERGENT MODEL

Tsunami Convergent Model is an innovative Land pooling technique used to acquire land required for the project within short period by involving all the Department Officials and Public Representatives duly analyzing that microscopic minority holding significant land tried to stall the process.

Counselling and awareness regarding the benefits of the programme created by the vibrant and robust network of SHGs of GHMC and a NGO SRACO (Society for Rehabilitation and Counselling Organization) with a proven expertise in social engineering and family/community counselling issues has been roped in. With extensive interaction with the stakeholders and IEC activities like Street plays by SRACO, "Chetana" awareness programme by Media, Counselling by Public Representatives all their apprehensions about the life in newly developed colonies from completion of project, allocation of dwelling units, management of the colonies etc., have been alleviated.

To reinforce confidence in the slum communities, a single and Common Possession Certificate is issued by the Revenue Department, wherein all the names of families evacuated from a slum for taking up 2BHK Housing project is enumerated in a single order. All these helped in convincing the citizens.

The construction of 2BHK housing units was initially proposed in in-situ slums and vacant / open lands within GHMC area. As a first priority, all the Government lands within the City have been enumerated. Construction of 2BHK housing units in peripheral areas of the City was also considered, which could help meeting the target.

All this made possible to pool up the land to an extent of 667.50 acres for implementing the Dignity Housing Project in GHMC.

DESIGNS, INNOVATIVE TECHNOLOGIES AND GREEN INITIATIVES ADOPTED

A well-engineered structure greatly minimizes the possibility of costly failures. Simply one can't make a building architecturally superb without a deep understanding about its structural planning and behavior. Structural elements in building are like skeleton in human that gives the strength as well as proper shape to make it perfect. Proper structural planning for a building makes it strong and cost effective.

Planning of structures being constructed under 2BHK Programme was done carefully keeping balance between safety and economy. Vertical construction strategy is adopted to accommodate more beneficiaries nearer to city as the available land is minimal.

Different plans/layouts are adopted at various locations based on the site conditions and availability as detailed below:

- i) Cellar+Stilt+9 floors (C+S+9) with 24 Dwelling Units per floor, 12 Dwelling Units per floor, 8 Dwelling Units per floor and 6 Dwelling Units per floor.
- ii) Stilt + Stilt +9floors (S+S+9) with 12 Dwelling Units per floor, 8 Dwelling Units per floor.
- iii) Stilt +5 floors (S+5) with 24 Dwelling Units per floor, 12 Dwelling Units per floor, 8 Dwelling Units per floor and 6 Dwelling Units per floor.
- iv) Ground +3 floors (G+3) with 24 Dwelling Units per floor, 12 Dwelling Units per floor, 8 Dwelling Units per floor, 6 Dwelling Units per floor, 4 Dwelling Units per floor and 2 Dwelling Units.

The Expertise of Jawaharlal Nehru Architecture & Fine Arts University (JNAFAU), has been utilized for the designs of 2BHK housing at Kollur Site where 15,660 DUs are proposed.

Fig. 1: 15660 DUs at Kollur II of Patancheru in S+10/S+11 Pattern

The structures are analyzed as Space frames using STAAD Pro/ETABS software. The appropriate loads and loads combination as per the relevant clauses in IS Codes are chosen for analysis and designs.

These structures are taken up with different technologies of constructions as detailed below:

i) Conventional Method

Most of the structures are constructed using Conventional Method. The columns and beams are analyzed as a space frame structure using STAAD Pro and designed for M25 Grade of concrete and Fe500 reinforcement.

ii) Shear Wall Technology

Shear wall technology (Construction of Walls and Slab using MIVAN Form work/ Tunnel form work).

MIVAN form work:

This technology is adopted at Dundigal site. Designs are proof checked by JNTU. The structure is analyzed using ETABS as a space frame considering the wall as a spandrel and pier and designed for M35 Grade of concrete and Fe500 reinforcement. Construction speeds are achieved faster due to lighter form work and less labor required for carrying the form work. Production cycle of 3 days can be achieved with higher precision in production of walls and slab units. However, 7-Day cycle was adopted for stripping of Form work. Plastering is not necessary because of the finish obtained.

Fig. 2: Construction of 864 DUs in S+S+9 Pattern at Dundigal using Shear wall Technology - Mivan Form Work

Tunnel form work

This technology is adopted at Rampalli site. Designs are proof checked by IIT Madras .The walls and slabs are monolithic to each other and accordingly the structure is analyzed using ETABS and designed for M40 Grade of concrete and Fe500 reinforcement. The use of rapid hardening concrete was proposed as it attains a compressive strength of 12Mpa within 24 Hours which allows faster de-shuttering and requires no plastering because of the finish obtained. Hence higher construction speeds are achieved. However, 3-Day cycle was adopted for stripping of Form work.

Fig. 3: Construction of 6240 DUs in S+10 Pattern at Rampally with Shear wall Technology - Tunnel Form Work

iii) Precast Technology

The structure is analyzed using ETABS as a space frame considering the wall as a spandrel and pier and designed for M35 Grade of concrete and Fe500 reinforcement.

The usage of precast technology in building construction is relatively new in our country. At present only IS 15916:2010 and National Building Code 2016 (Part 6 -Section 7) are the available Indian standards related to building design and erection using this technology. Designs are proof checked by NIT, Warangal.

The joints between precast elements i.e. the wall-wall joints, the wall-slab joints, the slab-slab joints are important for transmitting the loads coming on to the structure to the ground safely. Columns are casted upto parking floor levels and then Pre-stressed hollow core slabs with M40 grade are erected. As all the elements are prefabricated, higher construction speeds are achieved.

Fig. 4: Construction of 1512 DUs in S+S+9 Pattern at Dundigal using Precast Technology

In addition to the above said technologies, the following Green/Eco friendly initiatives were taken:

- i) Use of natural timber or wood is avoided.
- ii) Raw materials such as Fly-Ash bricks, fly-Ash blended PPC cements, Crushed Stone sand (Robo Sand) are used.

IMPLEMENTATION OF THE PROJECT

i. Policy Initiatives

- a. Relaxations of payment of EMD (1%) & FSD (3%) against 10% for other works.
- b. Supply of cement at subsidized rate of Rs.230/- per bag
- c. Sand is supplied at free of cost by TSMDC (Telangana State Mineral Development Corporation)
- d. Other State / Central Government registered contractors also made eligible to participate in tenders.
- e. Existing GHMC licensed Builders made eligible to participate in tenders.
- f. To accept the single tenders in the 1st call

ii. Physical & Social Infrastructure

Provision of physical infrastructure like adequate Drinking Water, Road Connectivity, Electricity supply, efficient Drainage and Sewerage systems are linked to existing schemes of the State Government.

Bus stops integration with Telangana State Road Transport Corporation (TSRTC), Fire stations to colonies, Open Air Gyms, Sports complexes, ATMs, CC Camera surveillance with support from Police Department. School Buildings, Primary Health Centers, Anganwadi centers, Public Distribution system centers, DWACRA buildings, Markets, Burial grounds, Cremation centers are planned to be developed along with Tree Plantation. Spaces have been earmarked for the above and these will be taken up under respective Government programs.

MAINTENANCE MECHANISM

Layouts are planned with revenue generating features like shopping malls or shops at stilt floor in order to partially meet the recurring maintenance expenditure towards lift, security, and housekeeping of common facilities making the Dignity Housing Project a self-sustainable model.

AWARDS & ACCOLADES

- i. Prime Minister's Award for Excellence in Public Administration 2018, for Excellence in Implementing Pradhan Mantri Awas Yojana".
- ii. Telangana Excellence Award, 2018 to the Commissioner, GHMC and team for the project "Land Pooling for 2BHK" by the Government of Telangana.
- iii. HUDCO Award, 2018 for Outstanding Contribution by GHMC in Housing Sector through various Innovative Initiatives.
- iv. HUDCO Award, 2019-2020 for Best Practices to improve living Environment under Housing, Urban Poverty and Infrastructure for 2BHK Dignity Housing at Kollur II in GHMC.

CONCLUSION

The Dignity Housing Project reached its culmination in the creation of better living standards by constructing 2BHK Houses with Civic and Social Infrastructure. The Houses completed are handed over to the eligible beneficiaries.

Tangible benefits of the projects are providing a spacious ventilated house with all amenities like piped water lines, sewerage system, community center, schools, etc. This leads to intangible benefits of improving the life style of the individuals and in turn achieving a self-reliant society.

ABSTRACT

Current projections indicate that 66 percent of the world's population will live in cities by 2050. Population equivalent to 7 (seven) "New Delhi" size cities is added per year to world's urban population. According to the data published by The Energy and Resources Institute (TERI), urban share of GDP in India will rise to 75% in 2030-31. Buildings represent around 40% of world's primary energy consumption. They are, therefore, directly responsible for increase in greenhouse gases and can play a key role in climate change adaptation. To achieve an energy efficient building regime, governments, businesses and individuals must transform the way buildings are designed, built and operated. Energy efficient buildings (new constructions or renovated existing buildings) can be defined as buildings that are designed to provide a significant reduction of the energy need for heating and cooling, independently of the energy and of the equipments that will be chosen to heat or cool the building.

The area of study is to develop understanding of high performing building envelope and drive adoption of energy efficient built to investigate and quantify the energy impact from the expected proliferation of important energy efficient solutions.

INTRODUCTION

Construction of building uses land, energy, water, and natural resources, and produces construction waste and releases greenhouse gases causing ecological imbalance. The buildings can develop the capacity to curtail GHG emissions and reduce the carbon footprint by incorporating building codes or rating systems in India. In a building. Energy audit reports and literature review indicates a typical break up of electrical energy consumption in Built Environment of commercial buildings is indicated in **Table 1**.

Table 1: Energy consuming areas in commercial building

Area of Consumption	Percentage Break-up
HVAC System	55%
Lighting	25%
Office equipments	15%
Other auxiliaries	5%

Heating, Ventilation and Air Conditioning system (HVAC) are energy guzzlers in any air conditioned commercial building. The purpose of a HVAC system is to create a comfortable environment by adjusting the four parameters of indoor air - temperature, humidity, air flow, and cleanliness, for the person inside the room/facility or product/process to meet requirement. Another high energy consuming section in building is lighting systems. Lighting not only provide a basic visual environment for occupants, but also have a significant impact on human health, work efficiency, and building energy consumption. Today, many people spend most of their day indoors. Therefore, it is important to create a comfortable visual environment to improve the living environment of the occupants and improve the efficiency of work.

Indoor environmental quality (IEQ) is the quality of a building's environment directly linked to health and comfort of occupants using that space. IEQ is determined by many factors including lighting, air quality, and damp conditions. Indoor environmental quality (IEQ) is a general indicator of the quality of conditions inside a building. It can also include functional aspects of space, for example whether the layout provides access to equipment when needed and whether the building has sufficient space for its occupants. In this regard it is necessary to address for thermal comfort, visual comfort and air quality etc. and their role in IEQ improvement.

Thermal Comfort

Thermal comfort in environment is important because discomfort in thermal conditions are potentially life-threatening for humans if the core body temperature reaches conditions of hyperthermia ($> 37.5\text{--}38.3\text{ }^{\circ}\text{C}$ or $99.5\text{--}100.9\text{ }^{\circ}\text{F}$) or hypothermia ($< 35.0\text{ }^{\circ}\text{C}$ or $95.0\text{ }^{\circ}\text{F}$). Buildings modify the conditions of the external environment and reduce the effort that our body needs to do in order to stay stable at a normal human body temperature, important for the correct functioning of our physiological processes.

Six primary factors that directly affect thermal comfort are defined as

- Metabolic rate
- Clothing insulation
- Air temperature
- Mean radiant temperature
- Air speed
- Relative humidity

Visual Comfort

Visual comfort is usually defined through a set of criteria based on the level of light in a room, the balance of contrasts, the colour ‘temperature’ and the absence or presence of glare.

Visual comfort is a reaction to the quantity and quality of light within any given space at a given time. It depends on our ability to control the light levels around us. Inadequate as well excessive light can cause visual discomfort. Changes in light level or sharp contrast can cause stress and fatigue due to human eye permanent adaption to light levels. It can vary depending on the following factors:

- Time of exposition,
- Type of light,
- Color of the eyes/ age of the person

Working in a window-less office, even under adequate light conditions, and working in an office with a view, are totally different experiences. Abundant scientific studies show positive impacts of the latter on mood and job satisfaction. A well-designed lighting system must provide adequate illumination to ensure safety and enable movement, contribute to visual comfort and facilitate visual performance and color perception. Monitored parameters include quantitative physical measures of the luminous environment (illuminance, luminance, daylight provision and glare) and qualitative aspects of vision (distribution, uniformity, color rendering, the spectral composition of radiation).

Air Quality

Indoor Air Quality (IAQ) directly affect over occupant health, comfort, and productivity significantly. Serious health impacts resulting from poor IAQ include Legionnaires’ disease, lung cancer from radon exposure, and carbon monoxide poisoning. More widespread health impacts include increased allergy and asthma from exposure to indoor pollutants (particularly those as associated with building dampness and mold), colds and other infectious diseases that are transmitted through the air and “sick building syndrome” symptoms due to elevated indoor pollutant levels as well as other indoor environmental conditions.

The two fundamental connections include the impact of ventilation on indoor pollutant levels and the impact on heating and cooling energy (sensible and latent). Given equation expresses the relationship between the outdoor air ventilation rate Q and the indoor pollutant concentration C_{in} for a single zone under steady-state conditions.

$$C_{in} = C_{out} + \frac{S}{Q} - \frac{R_{fac}}{Q}$$

Where C_{out} is the outdoor pollutant concentration, S is the indoor contaminant source strength, and R_{fac} is the rate at which the contaminant is removed by filtration or air cleaning.

This relationship shows that as the ventilation rate increases, the indoor concentration decreases (assuming $S > R_{fac}$).

The amount of energy E required to heat (or cool) and move the ventilation air is expressed as

$$E = \rho C_p Q \Delta T + \rho C_l Q W + E_{fan} - E_{hr}$$

where ρ is the air density, C_p is the specific heat of air, C_l is the air latent heat factor, ΔT is the temperature difference between indoor and outdoor air, W is humidity ratio difference. E_{fan} accounts for the energy associated with equipment used to move the ventilation air (e.g., fans), and E_{hr} is the energy recovered by heat recovery equipment.

Equation shows that as the ventilation rate increases, the energy required to heat (cool) the outdoor air also increases, but it also implies flexibility in how the air is delivered and through the use of heat recovery.

BUILT ENVIRONMENT AND ENERGY EFFICIENCY

Thermal comfort, indoor air quality and visual comfort have to be taken into consideration while designing an energy efficient and healthy building environment, as the overall goal is not just the deployment of such environments but also their overall acceptance by their occupants. The objective of developing low energy consuming or low carbon buildings is to increase the sustainability of the built environment while ensuring the long-term well-being of occupants. However, for an existing it is challenging to modify and redesign a building to meet thermal comfort, visual comfort and indoor air quality for low energy consumption. The field case study findings for energy use implications and adaptive models are discussed to develop clear depiction. There have been a number of studies investigating the energy use implications in the built environment. In this paper, we are briefly discussing measures focusing on performance assessment and approaches to improve energy efficiency of HVAC system in facility.

Sustainability of the Built Environment

Sustainable planning for a commercial building derived from thermal modeling of a particular site and the built environment. Several factors taken into account; sunlight path analysis, orientation of building, climatic conditions. The building shape and orientation are optimised reduce the heat to minimise the delta temperature outside and inside of the building thereby minimizing overall HVAC requirement. In a new building, planned and designed external cladding, insulation and glazing minimizes heat gain/ loss, increase natural ventilation and day light saving in and around the building.

To stop solar heat gain from roof, reflective coating material or installing light-colored roofing materials capable of absorbing, and not transferring, solar radiation should be provide. No other data available.

The energy performance of chiller systems depends on the heat rejection medium, ambient conditions, compressor efficiency and the load carried by each operating chiller. Instead of operating chillers at the same part load ratio, it is recommended to properly accounting for their part load performance characteristics, which maximize the entire system performance.

In an existing building, modifying and improving the chilled water lines, replacing the single glazed glasses with double glazed glass, improving the thermal insulation, is complicated and challenging. It is always advised to consider building envelope design, materials, thermal comfort with overall energy consumption during the construction phase of the building.

The behavioural change for setting higher indoor temperatures in summer-time lead to less prevalence of cooling systems. In situations/locations where air conditioning is unavoidable, a wider range of indoor thermal environment would mean less cooling requirements and hence less electricity consumption for the air conditioning systems.

Energy Efficiency of Built Environment

Maximum energy is consumed by HVAC systems and other chilling units. Some of the reasons for high power consumption and low efficiency are: Operating at low set temperature, Wrong selection of system (oversize or under size equipment), manual control of system, aged system and poor maintenance, choked filters. The poor insulation of the chilled water tank leads to heat gain in summer and more loads on chiller. With proper insulation, the heat gain from the storage tank can be reduced up to 2-5% based upon the ambient conditons.

Energy Conservation Act 2001 support the uptake of energy conservation practices for equipments and appliances announced under energy conservation building code, the adoption of energy efficient appliances and technologies and several rating system in India. The changeover to energy efficient appliances leads to lower energy consumption (reduction of up to 23% in households) and lower instantaneous electric demand.

Energy Efficiency and Recent Developments

Advanced IEQ control systems use learning-based methods, Rule-Based Control (RBC), Model based Predictive Control (MPC) and agent-based control systems. The application of Artificial Intelligence (AI) techniques and smart metering systems create intelligent buildings to improve energy efficiency, comfort, health and productivity of occupant in facility units. Recent domains of AI that are widely used in buildings are Computational Intelligence (CI) or soft computing and Distributed Artificial Intelligence (DAI). Selection of building climate control strategy is highly dependent on the available computational capacity. Appliances equipped with motion sensors or connected to an automatic centralized control system based on occupancy or utilization, bring higher reduction than conventional appliances and can result in a 10% reduction in energy consumption compared to appliances without any power control system or equipped with a standby mode.

Buildings equipped with recent lighting system like LEDs through out in their campus can lead to optimized use of lighting however, in the less occupied spaces there is a need of motion sensors. Buildings with centralized chiller plants may be provided with thermal storage facility for chilled water in the basements or in underground holes. Most of the commercial complexes require the HVAC system during day time so the buildings with thermal storage can operate their chiller plants during non peak hours and store the chilled water and same could be utilized during day time.

Sensors are used to collect data on environmental conditions to manage and operate a facility. These are distributed through the monitored spaces to collect relevant data. Wireless Sensor Networks (WSNs) are a promising technology that will upgrade the data collection and convenient to monitor. The sensors are coupled with actuators which are responsible for the system operation (blinds, lightings and heaters). Indoor environmental climate controls can be linked to immediate occupancy information.

DISCUSSION AND CONCLUSIONS

We have defined the factors that limit the interactions between occupants, IEQ and building design. It is crucial to respect the interdependencies in a human-built environment system for a successful design of healthy, energy efficient and comfortable indoor environment.

Energy consumption, conservation, and the impact of climate change are the upcoming challenges for the future IEQ research. The flexibility and adaptability on smart energy saving measures can be achieved through better built design during construction stage, automated building parameter control, behavioural change and tangible energy conservation measures. However, substantial uncertainties still exist in operation and maintenance, usage and monitoring. There is a need to create a structure enabling continuous training and awareness in the field of building technology and operation for users. The future building environment will be highly automated, based on artificial intelligence and prediction methods. It is believed that highlighted points in this paper will be relevant, especially concerning the emerging markets when it comes to building automation and that they will contribute to more human-centric and environmentally-conscious building initiatives.

✉ rajarshi.mukherjee@myworldmail.org

Keywords : Rectangular Parallelepiped, Drilling, Boring, Rotary Cam Milling, Tungsten Electrode Welding, Mild Steel Electrode Welding, Laser Beam Welding, Fighter Jets, Air-Borne Missile Launching Platforms, Single Turbine Aircraft, Twin Turbine Aircraft, Auxiliary Fuel Tank, Shortest Possible Time (SPT).

INTRODUCTION

This paper analyzes some of the Fighter Jets available in the world and in conjunction, discusses, if Rectangular Parallelepipeds can be turned, through simple machining and welding, into a mass production system, in the shortest possible time – SPT, of making Fighter Jets and Airborne Missile Launching Platforms.

This paper delves on simplistic manufacturing practices and an analysis of turning out a futuristic, simplified and alternative approach to design and manufacturing, leading to mass production systems for Fighter Jets and Airborne Missile Launching Platforms.

BODY

India should look at the Fighter Jets available with it, like, examples of MIG series Aircrafts which are a little nose down, Mirages we are not sure of and not too many India has, Sukhois have noses pointed more downwards compared to MIGs, HAWKS have noses pointed more downwards compared to Sukhois, the new induction Rafiels have the base flat and in a straight line but the nose a little pointed downwards. The basic design enlightens us to think of Air-to-Air combats, no fighter jet amongst these have a machine gun on the nose, every one of them has an electro-probe, and in the ATA combats, it is a motion like to keep the beaks straight in a Hen fight, the aircrafts will form a triangle in the motion and will crash into each other at some top-end of the triangle, the formed triangles varying from Aircraft to Aircraft, based on positioning of the noses.

This paper delves in simple manufacturing processes like drilling and boring and cam-milling to turn rectangular parallelepipeds into the structures' of Fighter Jets and Airborne Missile Launching Platforms and in the shortest possible time – SPT, with an idea of creating Mass Production Systems for the future. Some other manufacturing processes, simplistic of them, are involvement of Laser Beam Welding and Laser Cutting.

The processes are and can be broken down into some parts, like one set of drilling, boring and cam milling and the other set, die punching and then laser cutting, finally leading to laser beam welding.

We are dealing with the formation of the structures first, and hence we are moving to the process of rectangular parallelepipeds getting turned in Airframes, with limited operations and finally the wings on them.

SINGLE TURBINE AIRCRAFT

A rectangular parallelepiped, shown sideways and from the front.

Fig. 1: The schematic view of a rectangular parallelepiped

A rectangular parallelepiped first drilled and then bored. It actually resembles the frame of a single turbine aircraft.

Fig. 2: Drilling & boring a rectangular parallelepiped

Rotary Cam-milled after drilling and boring. The shape becomes circular on the outside.

Fig. 3: External Surface Rotary Cam-Milled

The cam-milled rectangular parallelepiped will look like a cylinder. This will house the turbine engine and the oil tank. It will form the structure for a single turbine aircraft.

Fig. 4: Rotary cam-milled surface

The top of the single turbine can be cam-milled whole length, or a portion left out any side, to laser beam weld the Cabin portion with the nose holding the machine gun. If cam-milled partially, the object will look like so.

Fig. 5: Semi-cam-milled into two sections of different diameters

The cabin portion can be shaped as below, in a trapezoidal form. The smaller side of the trapezoid holding the machine gun while the bigger side holding the Pilot(s) cabin. It can be Die Punched or Cone Casted.

Fig. 6: The cabin & machine gun section

Once the Cabin and the Basic turbine holding structure is formed, can be laser beam welded on the front, un-cam-milled portion.

TWIN TURBINE AIRCRAFT

The below diagram represents the basic shape of a twin turbine aircraft.

Fig. 7: twin turbine drilling & boring

SINGLE AUXILIARY TANK AND TWIN AUXILIARY TANKS

A single auxiliary tank or a twin auxiliary tank covers more distance.

Fig. 8: Auxiliary tanks for fuel

TWIN MISSILE CHAMBERS OR FOUR MISSILE CHAMBERS ON A SINGLE TURBINE WITH ONE AUXILIARY TANK

Depending upon Turbine weight towing capacity and wing span, the rectangular parallelepiped can be drilled and bored to carry two or four missiles, with one turbine one auxiliary tank or twin turbine two auxiliary tanks and wings laser welded to the sides.

Fig. 9: Twin or four missile chambers on single turbine & single auxiliary tank

TWIN MISSILE CHAMBERS OR FOUR MISSILE CHAMBERS ON TWIN TURBINES AND TWIN AUXILIARY TANKS

Fig. 10: twin or four missile chambers on twin turbine and twin auxiliary tanks

The above diagrams are a schematic view of what from the front, a single turbine or a twin turbine will look like, how a single or a twin auxiliary tank(s) will fill in, and how each one of them can carry a twin or a four missile system will look like. They are all born off simple machining processes like drilling, boring, cam-milling to get the round outer surface, simple laser cutter to put the machine gun on the nose and simple laser beam welding to add the cabin portion to the structure, noting it will be a single piece design with welded, and laser, cabin and wings. Laser welding is mentioned as it is better to Tungsten and Mild Steel conventional welding and the single piece structure forms the right airframe when speed and wind circulation in the atmosphere are concerned.

CONCLUSION

We hope this paper successfully discusses the simplest of manufacturing processes when used properly, can come out with complex objects like Fighter Jets and Airborne Missile Launching Platforms, a futuristic, simplified and alternative approach, and if thought out properly, can cause, mass production systems in shortest possible time – SPT, for India to be self-reliant in mass producing Fighter Jets and Airborne Missile Launching Platforms.

We hope we are not rubbing off shoulders of people currently involved in Fighter Jet designs, but we are trying to develop a futuristic, simplified and alternative thought process on if can be done, then we can try and evolve for the future of India where skies can be filled with too many of them and in too short a time, bordering on simplicity on mind and efficient work habits, inculcated through the maturity of thinking leading to some experimentations in practical.

We need to note the above discussion is on the formation of the structure without discussing on the wings for the Fighter Jets and the Air-borne Missile Launching Platforms, just laser beam welding the wings on the sides do.

ABSTRACT

The main objective of this paper is to induce a huge mass of turbulence intensity (T.I) in the test section of a low-speed wind tunnel using a passive turbulence grid. Inducing turbulence inside the wind tunnel is necessary to match the climatic boundary condition of airflow during testing. The rectangular frame of the grid is designed with the reference of the test section inner dimension. The different diameter tube with an alternative grid number is utilized to predict the possibility of generating a higher level of turbulence. In this manner, higher-order turbulence intensity ranging from 4% to 11% can be attained in the test section. Concern has also been given to the flow uniformity that has been verified using rake probe. The flow consistency is a required parameter for developing immense turbulence level. Details of the designed grid structure and outcome of turbulent intensity for various grid arrangement and grid location length scale are conferred in this paper.

Keywords : Turbulence intensity; Boundary layer stimulation; Passive grid; Wind tunnel; Pressure transducer.

ABBREVIATION

T.I -Turbulence Intensity in %

T.G. - Turbulence Grid

U_{∞} - freestream velocity in m/s

P_0 - Total pressure in N/m²

P_s - Static pressure in N/m²

h, b, w - height, base, a width of the designed T.G in cm

H, L, W – Height, Length and width of the tunnel test section in cm

T_u – turbulence level

n – Number of grid

l – Grid location length in cm.

INTRODUCTION

During stormy, the effect of shear stresses are considered at the height of 300m to 400m from ground level will be merely turbulent. This is called viscous sub-layer, a representation of very high wind shear. The earth surface with roughness components like grass, house, trees etc., makes flow with some swirls. Based on this intensity of swirl the velocity, temperature and all other properties of the flow are represented by entropy, momentum and velocities. Due to this purpose, while performing experiments inside the wind tunnel to calculate aerodynamic forces and other air properties, wind tunnel should have the capacity to generate the flow condition as nearly as possible to earth sub-layer, where the frictional velocity is nearly constant. This work is aimed to implement similarity theory using some turbulence generating grids to develop turbulent boundary layer wind tunnels. Several flow conditions are considered by a vast level of turbulence intensity. For the sample, the turbulent intensity level of 20% is gained in turbo machinery flows. Similar wind tunnel experiments are carried to trigger identical turbulent intensity, to reflect the turbulent induced flow rationally. Indistinct, the transition of the laminar-turbulent transition and heat transfer is largely indigent on the free stream level of turbulence.

The determination of the growth of boundary layer enhancement and aerodynamic performance criteria is strongly based on the transition effects. This flow transition depends on merged effects of more turbulence intensity and nearly less Reynolds number as common of high-speed turbo machinery flow. As a result, the replication of achieving similar turbulence levels is of most important for wind tunnel experiments. The perfectly constructed wind tunnel will reflect a very low level of turbulence in a free stream wind speed. Accordingly, a passive mode of turbulence generating grid is utilized to induce the posterior turbulence and change the mean-velocity distribution. Based on the action, the turbulence generators are clustered into two categories.

Passive Turbulence Generator

Generally, passive kind of turbulence generator, are used for raising the level of turbulence inside the wind tunnel test section. In this work, a frame with cylindrical pipe arranged in a grid manner act as a turbulent inducer. From the survey, introducing an appropriate combo of grid criteria (shape of the grid element, grid element width, etc.) helps to achieve a high level of turbulence reported by S. Arunvinthan et al. [1]. Passive kind of turbulent generator are the easiest way of inducing turbulence in wind tunnels. Grid with cylindrical tube produces eddies and the formation of vortices and these vortex effects to add turbulent energy to the flow at the downstream in the wind tunnel. The energy generated by the vortex comparatively has high frequency and breaks the large scale eddies to small scale. The rapid decay of energy in the downstream will takes place. The flow faraway behind the grid is described adequately by good uniformity and isentropic by Thorben Aufderheide et al. [2].

Active Turbulence Generator

The flow injection or introducing rotating parts or an array of winglets placing on a shaft are introduced behind the grid in an active mode of turbulence generator. These add-on parts generate a high swirl isentropic flow in the test section of a wind tunnel. With the aid of the active grid, developing shear turbulent and triggering turbulent boundary layer can be achieved. The active mode of the turbulence generator is complex for generating turbulence. The familiar technique to dominate the turbulence intensity in the wind tunnel is jet injection. The amount of turbulence generation depends on the injection ratio and direction. Review shows that a new method of the active mode of increasing turbulence is endless in research.

RESEARCH METHODOLOGY

Subsonic Wind Tunnel

The Low-speed wind tunnel of the aerodynamics laboratory at SASTRA Deemed to be University is utilized for inducing turbulence at the test section with and without the grid. The wind tunnel motor is rotated with the maximum horsepower of 10HP. The maximal free stream velocity is about free stream velocity $U_\infty = 60$ m/s. The freestream velocity of the airflow is controlled by the RPM regulator. The basic turbulence intensity at the test section of the tunnel is as $T.I \approx 0.1\%$.

Fig. 1: Subsonic wind tunnel facility in SASTRA Deemed to be University.

Pitot Static Tube

The pitot static tube fixed at the downstream of the wind tunnel test section approximately 125 cm away from the test section inlet collects the parallel (P_0) and perpendicular (P_s) direction of incoming flow in the test section used to predict the turbulence level of the flow.

Pressure Scanner

64 channel pressure scanner is used to sense the pressure from the pitot-static tube. The connecting tubes are used to link the Pitot static tube and the scanner. The data was captured with the transient recorder with the sampling frequency of 700 HZ.

Fig. 2: 64-Channel Pressure transducer

Turbulence Generating Grid

The frame of the grid is designed with the dimension of $h*b*w = 30cm*30cm* 2.5 cm$. Cylindrical PVC pipe of 2 cm and 2.5 cm in a count of five and six are fitted to the frame. Giulio Vita [4] figured out, if the velocity distribution rear to the grid is not homogeneous, this is due to the impact of turbulence generated by the bars. While choosing the number of the pipe some parameters like solidity factors play an important role. The empirical formula for designing a turbulence grid helps to construct perfect T.G. The ratio between the interference of bars and cavity of the screen is maintained to reduce the solidity factor. The huge solidity grid is not considered and for this reason in this paper, the porosity of the grid is limited within 40%.

The solidity factor of the grid is calculated by using (1)

$$\varepsilon = \left(1 - \frac{d}{g}\right)^2 > 0.5 \tag{1}$$

Where d is the diameter of the grid pipe and g is the distance between the bars.

The turbulence intensity can be theoretically predicted using the grid parameter using Ref. [4] as

$$T.I = 100 \frac{\sqrt{u'^2}}{\bar{u}} \tag{2}$$

Here, T.I turbulence intensity is the deviated velocity in the test section and \bar{u} is the mean velocity measured from the test section.

In this paper, a parallel-mesh grid is designed and tested by placing in vertical directions. This arrangement achieves aimed turbulence magnitude of about 12% with 25 mm diameter pipe with 6 tubes. The experiment carried by placing 5-6 number of tubes separated with an equal distance of $l/n=30/5$ and $l/n = 30/6$.

RESULT AND DISCUSSION

Wind tunnel calibration with and without grid

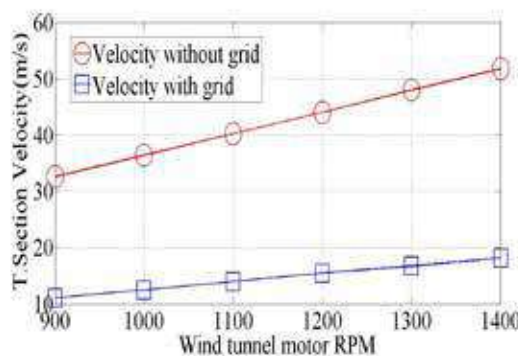

Fig. 3: Wind tunnel motor RPM vs velocity in the test section

The calibration carried out with and without placing the turbulence grid. The mean-flow velocities are measured 90% far away from the test section inlet using Pitot - static tube connected to the pressure scanner. From Fig. 3, after introducing the

turbulence grid the velocity inside the test section has been reduced 65% of the free stream velocity, this is stated theoretically in (2). This is due to the formation of turbulence generation by the grid placed at the test section inlet.

Effect of the number of grid

The Intensity of turbulence has been calculated by arranging a PVC pipe in a parallel mode in the vertical direction. To increase the level of turbulence the grid number is increased from 5 to 6, separated by an equal spacing of $L/n=30/5$ cm, $30/6$ cm.

Table 1 : Variation of velocity and turbulent intensity based on grid number and grid size

S.No	The grid at test section inlet	T.S Velocity(m/s)	T.I %
1	5 G, 2 cm Dia.,	23	3
2	6 G, 2 cm Dia.,	14.5	7.14
2	5 G, 2.5 cm Dia.,	14	6.8
4	6 G, 2.5 cm Dia.,	11	12

From **Table 1**, it can be stated from increasing the number of the grid the turbulence level has been increasing twice but the velocity at the test section is reduced half a time of free stream velocity. Even, increasing the diameter of the grid pipe results in increase 60% more T.I.

Location of Grid

The Turbulence grid with 5 and 6 number of pipe are placed at various length ratio (l_r), $l_r=l/L$. Where L is the test section length (150 cm), l is the grid location from the test section inlet. The value of l is varied by placing by placing T.G at 5cm, 10cm, 15 cm, 20cm, 25cm and 30cm.

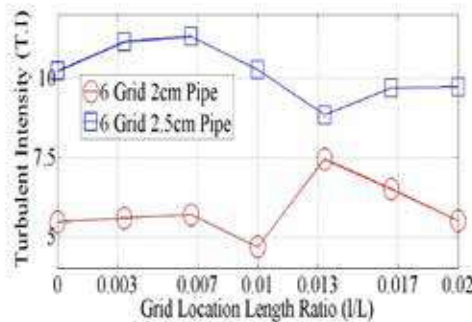

Fig. 4: Variation of the intensity of turbulence along with the grid location with various grid diameter

Fig. 4, gives a detailed view for the results of passive turbulence grid, the results pointed out that turbulence intensity does not vary much only when placing the grid at various location along the test section length. This is because on placing grid at $l/L=0$, results in 5.2% turbulence intensity the same 5.4% of T.I is obtained when placing the grid at $l/L = 0.02$. The placement of the grid is not a considerable parameter in turbulence generation technique. However, increasing the grid pipe diameter from 2 cm to 2.5 cm, the maximum turbulence intensity level of 11.5 % is achieved. Hence the T. I depend strongly on pipe diameter.

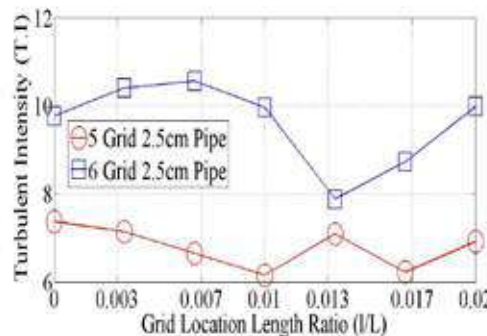

Fig. 5: Variation of the intensity of turbulence along with the grid location with varying number of the grid.

Predicting T.I by increasing number of grid pipe from 5 to 6 count separated by equal spacing, the intensity of turbulence increases to 25%. Thus increasing number of grip pipe results to increase turbulence intensity to 35% from **Fig. 5**, while choosing several pipes, solidity factor should be considered.

Fig. 6 Flow uniformity check with and without grid along the y-direction

Commonly, the airflow inside the wind tunnel test section is homogeneous throughout, the flow is aligned to the test section and has fully laminar by Junsik Lee et al. [5]. Though the quality of airflow is to be checked, hence the regulation of flow is checked out to measure the amount of irregularity in the airflow. The velocity along the y-direction of the tunnel is measured using the Rake tube. Fig. 6, shows the velocity seems to be equal throughout the height H of the tunnel before and after introducing the turbulence generator grid. This result favours well for the future work for predicting aerodynamic properties for any model under this predicted turbulence intensity generated using this designed turbulence generator grid.

CONCLUSION

A passive mode of generating turbulence by designing a turbulence grid acts as a disturbance to the incoming free stream flow results to a greater quantity of turbulence. This consequences to stimulate atmospheric boundary condition inside the test section of the wind tunnel. The tested turbulence generating method achieves a maximum of 11.5% of maximum intensity. The intensity of turbulence completely depends on the freestream velocity. From increasing grid number from five to six, the T. I is raised to $\Delta T.I = 25\%$. From rake tube, the velocity distribution test result proves the proper homogeneity of the flow in the test section. The tried design of wind tunnel with turbulence generation grid will be perfectly suitable for future construction of boundary layer wind tunnel.

ABSTRACT

Flow past a grooved rotating circular cylinder placed in a uniform stream is investigated via numerical simulations. The Reynolds number based on the cylinder diameter and the free stream velocity is 0.4×10^5 . The effect of grooves on the cylinder is analysed on various Groove Ratio GR ((no. of grooves)*perimeter of groove/circumference of cylinder) and Spin Ratio α (surface speed of the cylinder/free stream velocity). The cylinder is rotated for 100 rpm and 200 rpm. The C_D and C_L are plotted with different Groove Ratio for two Spin Ratio. The variation of C_D and C_L with Flow time are also plotted. The results are compared with the Smooth (no groove) cylinder on same conditions. The study revealed that the presence of grooves on the cylinder considerably reduces C_D and increases C_L . As the Groove Ratio decreases, C_D decreases for both Spin Ratio. The C_D remains almost same for both Spin Ratio. Furthermore, pressure contours and velocity streamline have been plotted to understand the flow for smooth and grooved rotating circular cylinder on various Groove Ratio and Spin Ratio.

Keywords : Groove Ratio; Spin Ratio; Circular grooves; Groove Depth Ratio.

INTRODUCTION

Flow past a rotating circular cylinder placed in a fluid flow finds many engineering applications. Due to periodic fluid flow, the shear layer separates from either side of the cylinder and develops vortex shedding in the downstream of a cylinder. This vortex shedding causes fluctuating forces on the cylinder which would result in structural vibrations. So, it is essential to control these effects in order to effectively implement it in engineering applications.

The variation of coefficient of drag (C_D) and lift (C_L) of a rotating circular cylinder in a uniform flow have been reported widely in the literature [1]. Unlike smooth stationary cylinder, the smooth rotating cylinder modify flow patterns and reduces flow-induced oscillation from vortex shedding in a viscous uniform flow. However, the Spin Ratio has a great effect on flow separation and formation of vortex shedding. The vortex shedding activity occurs from $\alpha = 0$ to $\alpha \sim 1.95$, after which it is suppressed [2]. Surprisingly, it again resumes in the range $4.34 < \alpha < 4.70$ [1]. In addition to Spin Ratio, Reynolds number is found to have a strong effect on wake morphology behind the cylinder. The presence of grooves on the cylinder has a significant effect on controlling the vortex shedding pattern. The coefficient of drag is reduced when the grooves are made on the cylinder [3]. Due to presence of grooves, the shear layer remain contact on either side of the cylinder and helps in controlling the flow separation. The aerodynamic performance of grooved rotating cylinder is higher than the smooth rotating cylinder. The variation of C_D and C_L with different groove depth have been reported in the literature. However, the aerodynamic characteristics of grooved rotating cylinder with different Groove Ratio have not yet been reported. Therefore, in the present study, the aerodynamic characteristics of grooved rotating cylinder with different Groove ratio are studied via numerical simulation.

The current work is aimed to study the variation of coefficient of drag and lift with different Groove Ratio for Spin Ratio $\alpha=0.03, 0.06$ corresponding to the cylinder rotation 100 rpm and 200 rpm. The pressure and velocity contours are plotted for GR to understand the flow and wake morphology. The results from the grooved rotating cylinder are compared with the smooth cylinder to obtain the aerodynamic characteristics.

NUMERICAL METHODOLOGY

Geometry

We have modelled cylinder with circular grooves on its cross-section by varying no. of grooves. The Groove Ratio (GR) is defined based on the number of grooves, perimeter of the groove and cylinder. Different models have been made according to GR. **Table 1** shows the geometry of cylinder with different GR. For present study, the Groove Depth Ratio GDR (depth

of groove/radius of cylinder) of 1:7.5 is chosen which turns out the depth of the groove to be 4 mm. The specification of the cylinder is illustrated in **Table 2**.

The Smooth Cylinder (no groove) of same diameter and length is used as reference model. For smooth cylinder, GR is zero. The variation of C_D and C_L have been measured and compared the results with the grooved cylinder of different GR. The two parameters C_D and C_L have been computed with variation in GR = 0, 0.8, 1.067, 1.2, 1.3, 1.6 corresponding to the no. of grooves 0, 6, 8, 9, 10, 12. These conditions are measured for Spin Ratio $\alpha = 0.03, 0.06$. The following are the new parameters defined for this paper.

1. Groove Ratio GR = (no. of grooves)*(perimeter of groove/circumference of cylinder)
2. Groove Depth Ratio GDR = depth of groove/radius of cylinder
3. Spin Ratio α = surface speed of the cylinder/free stream velocity

Mesh and Boundary Conditions

ANSYS FLUENT has been used for the computational study and the post processing analysis of the model. The rectangular domain has been generated with 500 mm along x-axis, 300 mm along y-axis and 188.49 mm along z-axis. The model is placed at 170 mm from inlet and 180 mm. The generated mesh for different grooved cylinder ranges from 3×10^5 to 8×10^5 mesh elements. Tetrahedral elements have been used for all models so as to maintain uniformity. The meshing is done in such a way that the mesh is extremely fine near the cylinder and the mesh size increases gradually away from the cylinder. The mesh independence is checked before running the simulation. **Table 3** shows the boundary conditions for the flow simulation.

Table 1: Geometry of cylinder

Table 2: Specification of cylinder

Parameter	Value
Cylinder diameter	D = 60 mm
Cylinder length	L = $\pi D = 188.49$ mm
Groove depth ratio(GDR)	1:7.5
Groove depth	d = 4mm

Table 2 : Boundary conditions

Position Condition	
Inlet Uniform velocity inlet (velocity magnitude = 10.413 m/s)	
Outlet Pressure outlet	
Moving wall Speed of rotation = 10.4719 rad/s (100rpm) = 20.9439rad/s (200 rpm)	
Model	Viscous
Frontal area	$LD = \pi D^2 = 11309.7 \text{ mm}^2$

RESULTS AND DISCUSSION

The variation of drag and lift coefficient with Groove Ratio for two Spin Ratio has been studied. The results of the grooved cylinder are compared with smooth cylinder. This helps in gaining a better understanding of the aerodynamic performance of the different models.

Coefficient of Drag(C_D)

The variation of coefficient of drag is plotted with GR = 0, 0.8, 1.07, 1.2, 1.3, 1.6 for $\alpha = 0.03, 0.06$. It is inferred from the graph that C_D remains almost same for both α . For both Spin Ratio, C_D is maximum for smooth cylinder and least for GR = 0.8 grooved cylinder. As the GR increases from 0.8, C_D increases for both $\alpha = 0.03, 0.06$. The C_D for all grooved cylinder is less than the smooth cylinder. **Fig 1, Fig 2 and Fig 3** shows the variation of C_D with different GR and Flow time for both Spin Ratio.

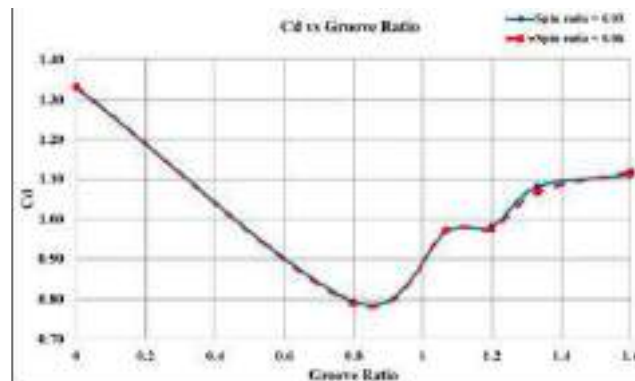

Fig. 1: Coefficient of drag vs Groove Ratio

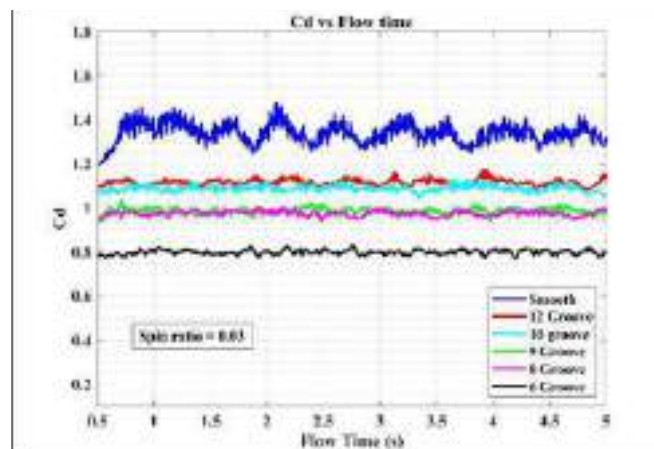

Fig. 2: Coefficient of drag vs flow time

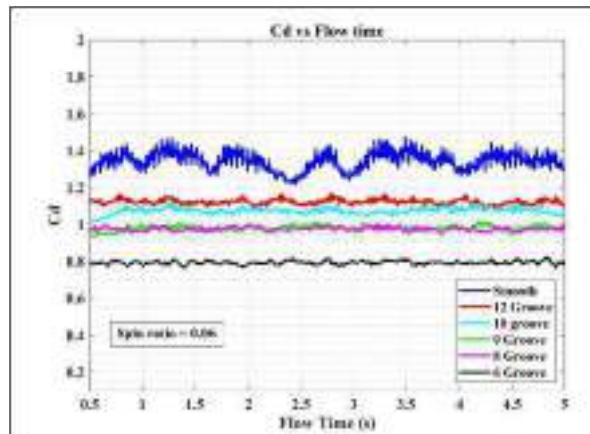

Fig. 3: Coefficient of drag vs flow time

Coefficient of Lift (C_L)

The variation of coefficient of lift is plotted with $GR = 0, 0.8, 1.07, 1.2, 1.3, 1.6$ for $\alpha = 0.03, 0.06$. It is inferred from the graph that C_L increases with increase in α for smooth and grooved cylinder. For both Spin Ratio, C_L is maximum for grooved cylinder with $GR = 1.2$ and least for smooth cylinder. The C_L for all grooved cylinder is more than the smooth cylinder. The variation of C_L with Flow time is also plotted for different GR which follows the same.

Therefore, these reduced C_D and increased C_L imply a better aerodynamic performance compared to the reference model (smooth). The presence of grooves makes the grooved cylinder models a better one compared to the smooth cylinder. Fig 4, Fig 5 and Fig 6 shows the variation of C_L with different GR for both Spin Ratio.

Velocity Streamline ($\alpha = 0.03$)

Fig. 10: Velocity streamline of smooth cylinder

Fig. 11: Velocity streamline of 6 groove cylinder

Fig. 12: Velocity streamline of 9 groove cylinder

CONCLUSION

The simulation results for a Grooved and Smooth Cylinder revealed the following:

1. The drag coefficient remains almost same for both Spin Ratio.
2. The drag coefficient is maximum for smooth cylinder and minimum for grooved cylinder with $GR = 0.8$
3. The lift coefficient increases with increase in Spin Ratio.

4. The lift coefficient is minimum for smooth cylinder and maximum for grooved cylinder with $GR = 1.2$
5. For all grooved cylinder, drag coefficient is less and lift coefficient is more than the smooth cylinder for a subcritical Reynolds number 0.4×10^5 .

The results have proved that the presence of grooves on the cylinder led to an increase in aerodynamic performance. Further studies have to be done to understand the aerodynamic characteristics based on different Reynolds number, Groove Depth Ratio and Type of Groove for several Spin Ratio.

Optimum Satellite Access Techniques “TDMA / SCPC or PSMA” For Next Generation VSAT Networks

Y S Rayudu

Dy General Manager, D&E-Coastal Surveillance System/NS-2, Bharat Electronics Ltd., Bangalore

✉ rayuduys@bel.co.in

ABSTRACT

In this paper multiple Satellite Access technologies discussed in detail with respect to protocol over heads, and its salient features, for next generation Satcom networks ie Coastal Surveillance VSAT network is considered as case study. The misconception of “Time Division Multiple Access (TDMA) for IP data, Single Channel Per Carrier (SCPC/MCPC) for serial data” existed earlier in Satcom industry studied quantitatively. This misconception existed earlier, due to SCPC manufacturers’ were offering Serial interfaces as default and IP Interface as add-on card, but Nowadays all Non TDMA systems such as SCPC and MCPC (Multi Channel Per Carrier)/PSMA(Packet Switching Multiple Access) based modem equipment manufacturers are offering Modems with IP interface as default interface due to wide acceptability of IP applications’ . SCPC and TDMA systems treat user data as series of bit streams without carrying any routing information in its packets. PSMA is true IP based VSAT network technology in which Data packets also carries information about the connection and services including Source and Destination addresses, Priority, Security, and Applications. PSMA processes the connection information and forward each packet over the sky to the required destination modem. As CSS (Coastal Surveillance Services) VSAT network is multi hierarchical hybrid network with bursty, fluctuating user traffic, PSMA with Adaptive Bandwidth on Demand (ABOD) with Capability of Connectivity Management will be the ideal choice.

Keywords : CSS VSAT Network, PSMA , TDMA, SCPC.

INTRODUCTION

It has been for quite a number of years since Ethernet interfaces and IP transport have been available on most, if not all base band satellite communication equipment’s in the industry, there was a misconception of “Time Division Multiple Access (TDMA) is for IP data, Single Channel Per Carrier (SCPC/MCPC) is for serial data .In this paper it is attempted to clarify this misconception by taking one typical case study of Coastal surveillance VSAT network.

This misconception was due to, earlier SCPC manufacturers’ were offering Serial interfaces as default and IP Interface as add-on card, but Nowadays all Non TDMA-TDMA systems like SCPC and MCPC/PSMA based modem equipment manufacturers are also offering Modems with IP interface as default interface due to wide acceptability of IP applications.

TDMA and SCPC can carry IP data traffic, but both the technologies treat user traffic packets as bit streams and do not use any information carried in IP packets.

Packet Switching Multiple Access (PSMA) is the only true IP based VSAT network technology in which Data packets carries rich information about the connection and services including Source and Destination addresses, Priority, Security, and applications. PSMA processes the connection information and forward each packet to different modem accordingly, similar to the function of a IP route.

CASE STUDY: CSS VSAT NETWORK

Coastal Surveillance VSAT network is the integrated real time Chain of Static Sensors project established to safe guard entire Indian coast including Andaman Nichobar and Lakshadweep Islands. CSS network established in the form of Remote Radar Stations (RS) with Electro-optic Surveillance Systems at close to 100 remote locations, 15 ROS’s (Radar operating Station) stations, Five ROC (Regional Operating Center) and Control Center. ROS will be receiving data from the connected RS stations. After processing (correlation) the data will be further linked to the Coast Guard Regional Headquarter (RHQ) known as (ROC). All ROCs will be further connected to the main control center.

VSAT network at the main land locations served as backup network for primary leased line network and surveillance data will be transported through VSAT automatically without user intervention when leased line fails. VSAT network at Island

locations served as primary connectivity network and surveillance data will be transported through VSAT. In order to make VSAT connectivity availability on 24x7 basis, technology required to choose with state of art technology with multi nodes , multi hierarchal and multi technologies which has sufficient link margins as some of the sites are very remote and at the places where satellite foot prints are weak .

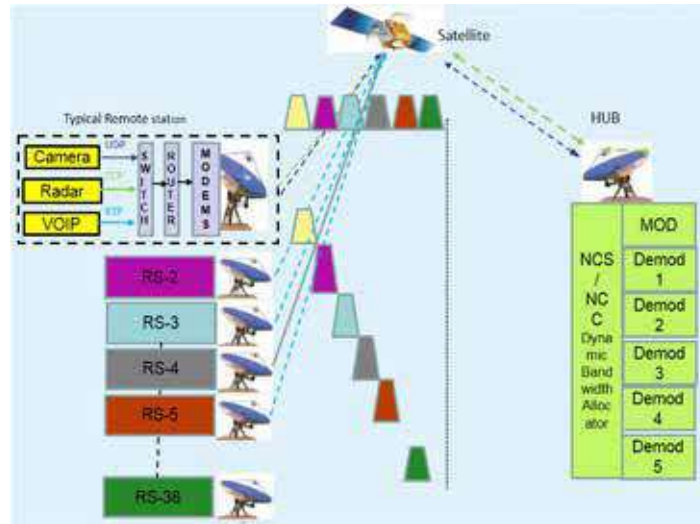

Fig . 1: Typical TDM/TDMA or TDMA/TDMA based VSAT Network

Table 1: Bandwidth requirement at remote station

Sl. No	Description	Bandwidth required (Mbps)
1.1	Data Rate required for Radar sensor	0.5
1.2	Data Rate required for EO/camera System	1.0
1.3	Data Rate required for VHF,MET data sensors	0.2
1.4	Overhead (Protocols, Encryption etc)	0.2
Total Bandwidth required from Remote Radar station		2.0

1. Data rate from each RS Radar station is 2 Mbps.
2. 50 % of Data at ROS need to uplink to ROC
3. 50 % data at ROC need to uplink to CC (25 % of RS sites data)
4. Multi layer architecture with Echelon feature ie when intermediate ROS station fails, RS data required to reach ROC station using over the air dynamic routing protocols.

Typical ROS station with five RS stations as shown in fig 1 is considered for case study in order to identify optimum technology for CSS Network by listing pros and cons of each system. In order to utilize the full advantages of TDM /TDMA offerings i.e. multiple remote sites utilizing same carrier by bursting (Transmitting) at higher rate i.e. 4 to 5 times than actual data rate required by the remotes. This feature will enable other sites to use same carrier at different time slots yet seamless data transfer is ensured.

For example if the data rate required from a typical remote (R1) is 0.4 Mbps then five (5) such remotes can transfer data seamlessly by bursting at 2 Mbps by each remote at different time slots. Remotes (R1, R2, R3, R4 and R5) will burst at next time slots i.e.

$$T1=T0,$$

$$T2= T1+T/5,$$

$$T3=T2+T/5,$$

$T4=T3+T/5$,

$T5=T4+T/5$ respectively.

Any VSAT network with such data requirements i.e. sub 1 Mbps data rate exists, user can comfortably utilize the advantages offered by TDM / TDMA technology like bank ATMs etc where data requirement from each ATM machines/ SCADA based remotes will be in the order of few Kbps.

But data rate required from each remote station of Surveillance system will be typically in the order of 2 Mbps due to presence of bandwidth hungry signals like cameras etc. So in order to utilize TDM / TDMA full advantage, user required to configure modem to burst at 10 Mbps though the data rate required per remote is 2 Mbps.

Nowadays most of the applications are demanding carrier rates in the order of 2Mbps/4 Mbps /8Mbps/10 Mbps due to user content is IP centric with video, Audio and Data services.

Whether TDMA technology for such high carrier data rate is appropriate? One must analyze quantitatively instead of qualitatively before choosing appropriate (right) technology.

It may be noted that DOT guideline does not permit to transmit more than 2 Mbps data from the remote sites with 2.4 Mt/ 3.8 Mt Antenna. It may be noted that accommodating bigger size antennas at remote places is not feasible due to cost implications and non-availability required real estate at remote places is real issue to accommodate bigger antennas at proposed (RS sites). So with the proposed antenna sizes at remote RS stations, user cannot take the advantages of TDM/TDMA Access mechanism systems for CSS kind of traffic.

MULTIPLE SATELLITE ACCESS MECHANISMS

Data through put efficiency of TDMA / SCPC or PSMA Systems are studied in detail and same is tabulated , shown in **Fig.2** which enable user to adapt appropriate technology based upon applications.

Fig. 2: TDMA / SCPC or PSMA systems

TDMA-TDMA, TDM/TDMA Systems

Efficiencies offered by TDMA-TDMA Systems (Typically around 75 %) which can be tolerable, where user data to be transported per Node is in the order of sub 1 Mbps (64 Kbps/128 Kbps/512 Kbps i.e. less than 1 Mbps) with true Bandwidth On Demand (BOD) feature i.e. burst demodulation. With this TDMA access mechanism precious 25 % satellite bandwidth forced to utilize for framing overheads which are inevitable with TDMA systems. This inefficiencies can be tolerable, if the user IP data rate required from the remotes are sub 1 Mbps, then one can think of TDMA

SCPC Systems

SCPC systems will be suited for applications where user data to be transported per Node is high but number of nodes in the network are limited and no true native Band width on demand feature is required.

MCPC/PSMA (Packet Switching Multiple Access) Systems

Such systems are very efficient true Bandwidth on Demand satellite access mechanism which will transport user payloads with near zero or bare minimum over heads, (< 2%). In other words PSMA (Packet Switching Multiple Access) is the true IP based VSAT network technology with efficiencies better than 98 % and in which Data packets also carries information about

the connection and services including Source and Destination addresses, Priority, Security, and applications. PSMA processes the connection information and forward each packet over the sky to the required destination modem accordingly. PSMA based satellite modem will act like a switch in the Sky (True IP based layer 3 Switch in the Sky), unlike most of existing VSAT networks are layer-2 networks WAN side .

SALIENT FEATURES OF PSMA TECHNOLOGY

This next generation Technology realize, True bandwidth on demand feature by a mere 48 Kbps signaling channel for entire network and each site is assigned by NCS . a carrier which is transport to user pay load data with zero overheads which enable to realize ~99% overall data throughput efficiencies. This feature will help in saving precious satellite bandwidth over 30 to 50 % over existing TDMA-TDMA technology.

Adaptive Bandwidth on Demand (ABOD) feature with Connectivity Management which improve bandwidth efficiency by Streamlining burst and fluctuating user traffic which is very much applicable for CSS type of traffic. Tighter Roll-off factors of 5 % compared with existing modems which are with 20 % roll offs will further reduce satellite bandwidth by another 15%.

Fig. 3: Adaptive bandwidth on demand (ABOD)

PSMA Modems with LDPC Forward Error Codes will require 2.5 to 3 dB lower Eb/No than the existing MFTDMA modems which are with TPC(Turbo Product Code) Forward Error Codes for the same BER (Bit error rate) of 1×10^{-8} . This additional 2.5 to 3 dB advantage in Eb/No will further increase link margin which will help in maintaining VSAT remote sites where satellite foot prints are poor.

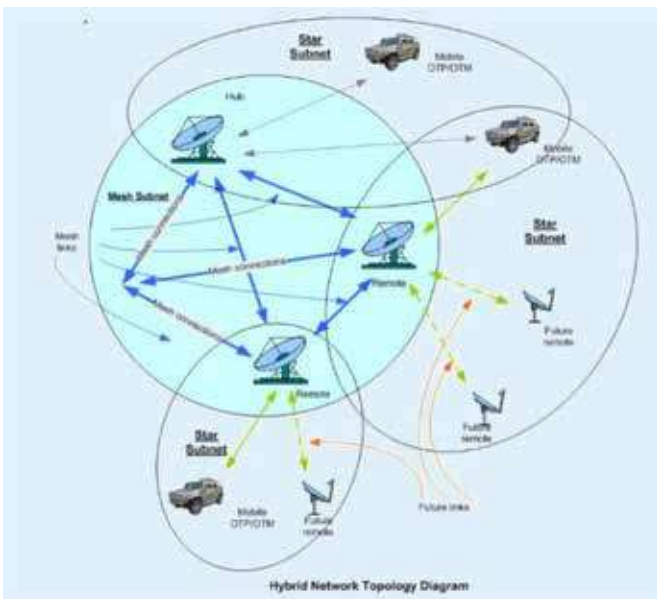

Fig. 4: Hybrid Network Topology with connectivity control Diagram

Proposed modem technologies supports, higher modulation like 16QAM / 32QAM. Use of Higher modulation like 16QAM compared with QPSK/8PSK will further saves bandwidth by 50 to 100 % at places where 7.5 Mt antennas are used will save satellite bandwidth by another 100 % from QPSK to 16 QAM.

The following are the advantages of next generation VSAT systems using PSMA multiple access techniques:

1. Continuous wave carriers with zero multiplexing overheads results in higher overall efficiencies up to 99%
2. Lower carrier spacing's (Tighter Roll off) up to 5 % instead of existing 20 %.
3. ABOD (Adaptive Bandwidth on Demand) feature further improves efficiency more than 30 %
4. Packet compression feature further reduce data rate requirement which is yet another Bandwidth efficiency feature
5. Connectivity control feature added network flexibility.
6. Dynamic Routing over Satellite (True Switch in Sky)
7. User Configurable network structure for dynamic connectivity which enable to accomplish mission critical , dynamic war scenario situations where technology should not become limiting factor.
8. As PSMA technology has bare minimum (less than 2 %) overheads on the user data rate, Total data rate requirement will reduce drastically which enable to use lower Power BUC (Block up converters) from remotes. Lower Power BUCs are more reliable and over cost of VSAT network can come down.
9. By adapting latest Forward Error codes such as LDPC(Low Density Parity Check) , advanced features such as AUPC (Automatic uplink power control) and ACM (Adaptive Coding modulations) will enable to achieve higher link margins which will help to maintain network 24X7 even during signal degradations due to pointing inaccuracies developed over period of time and atmospheric variations.
10. Smaller remote antennas can suffice, for user BER (Bit Error Rate) requirements which avoids requirement of complex Antenna control units.
11. As this next generation SATCOM modem require lesser bandwidth more number of VSAT nodes for given Bandwidth (More Concurrency) can serve through VSAT within allocated Bandwidth or it can reduce the satellite Bandwidth typically by 40 % to 50 % for same number of concurrency requirements.

COMPARISON OF PSMA WITH EXISTING TDMA SYSTEMS

Table 2: Comparison of psma & existing vsat

Features	PSMA VSAT	Existing TDMA VSAT
No. of Carriers	One carrier per site	One shared among multi-sites results higher data rate per site
Carrier Rates	Vary and On-Demand, from 8 kbps to 22/40 Mbps	Pre-Fixed at rates 256/ 612.5 kbps / 1.25 / 2.5 / 5 Msps.
Data Throughput	Same as Carrier Rates.	Only Fraction of carrier rates
Carrier Activation	On-Demand and Continuous and adptive Bandwidth on demand	Frequent Bursts in the order mille seconds
FEC (Forward Error Correction)	Supports LDPC which require 2 to 2.5dB lesser Eb/No	Supports Turbo FEC only by existing MFTDMA systems which does not support LDPC.
Channel Efficiency	Near to 99%, throughput=carrier rate	50-75% (Sometimes lower than 50% avg.)
MCPC Multiplexing	Layer 2& 3 Routing	TDMA Mux
Latency	Typical 500 ms round trip delay	Typical 650 ms round trip delay
Connectivity	Unlimited supports Star / Mesh / Hybrid)	Single Topology (Star or Mesh)
Network Expansion	Unlimited	Limited by TDMA Carrier Rate
BUC and Antenna Size	Smaller Antenna sizes with lower power BUC can provide comfortable Link margins.	Higher antenna sizes are required in ordered to maintain same BER(Bit Error Rate) which add additional cost.

CONCLUSIONS

Next generation VSAT networks such as CSS (Coastal surveillance system require multi hierarchical, multi node complex hybrid network unlike simple Star or mesh alone network. Due to its complexity, CSS VSAT network, ideally will be requiring high efficiency technologies like PSMA with Adaptive Bandwidth on Demand feature with connectivity control feature. Selection of optimum satellite access technology for CSS will be very much important, in view of number of nodes are 125 + nodes and needing satellite bandwidth in excess of 2 + transponders.

Lastly , the total cost (Capital & Operational expenditure i.e. CAPEX & OPEX) of each solution with respect to precious satellite bandwidth, System reliability and ease of maintenance will play vital role in selecting right technology for given user requirements.

Electromechanical Behavior of Graphene-based Composite Plate with Flexoelectric Effect

K B Shingare, S Naskar*

Department of Aerospace Engineering, Indian Institute of Technology Bombay, Powai, Mumbai

✉ susmitanaskar@iitb.ac.in*

ABSTRACT

In this paper, the derivation of an exact analytical solution of nanoplate using Navier's method and Kirchhoff's plate theory is investigated. The electromechanical behavior of simply supported graphene-reinforced composite plates accounting the influence of size-dependent properties under the uniformly distributed load is investigated. So, the analytical results obtained from the present study show that the influence of size-dependent properties such as piezoelectric and flexoelectric effect on the nanoplates' piezoelectric response is substantial with respect to thickness of plate. The electromechanical response including maximum deflection and resonant frequency of graphene-reinforced composite plates shows significant enhancement when compared to the conservative composite plate. Outcomes of present results reveal that effect of flexoelectricity on static and dynamic characteristic of composite plate is noteworthy and cannot be neglected.

Keywords : Graphene, Flexoelectric effects, Nanocomposite, Nanoelectromechanical.

INTRODUCTION

In the past few decades, the discovery of piezoelectric composite structures has paid huge interest in the research communities to predict their properties and possible use such as nanoelectromechanical systems (NEMS) application such as sensors [1], actuators, electric switches, nano-generators, transistors, energy harvester, and distributors [2] for the active control of high-performance lightweight smart structures subjected to static and dynamic loading [3]. The effect of piezoelectricity was first observed in 1880 by P. Curie and J. Curie [4]. Piezoelectric material has the property to generate electrical polarization in response to the homogeneous strain and vice versa. Whereas, in 1957, Mashkevich and Tolpygo observed the effect of flexoelectricity [5] and defined as the spontaneous polarization to an applied strain gradient can be called as direct flexoelectric effect, which is coupling between the electric response (in terms of polarization or electric field) and gradient of mechanical responses. Numerous studies were carried out so far to explore the effect of piezoelectricity in bulk materials and recently, exploitation of nanomaterial has attracted the researchers interest significantly to study the effect of the piezoelectricity in the different materials. However, due to the homogeneous strain, the piezoelectric effect unable to improve the size-dependent characteristics of piezoelectric nanostructures, in such cases by breaking the inversion symmetry, non-piezoelectric dielectrics nanostructures can also be polarized this phenomenon of breaking inversion symmetry to polarized non-piezoelectric dielectrics is named as flexoelectricity [6]. The recent advancement of nanoscale technologies has captivated the attention in flexoelectricity since the large strain gradients frequently exist at the nanolevel may cause to flexoelectric effect.

The ground-breaking experimental analysis concerning to 2D single layer of graphene by Novoselov et al. [7] has engrossed massive response from researchers and scientists because of its distinctive mechanical strength, electrical conductivity, thermal conductivity. Recently, Shingare and co-authors [8]–[12] studied the electromechanical response of graphene-based nanocomposite (GNC) and its structures such as beam, plate, shell and wire by incorporating piezoelectric nanoscale graphene fiber in polyimide matrix. In this, they assumed graphene as nanoscale fiber and found effect of size-dependent properties such as piezoelectricity, flexoelectricity and surface effect on these GNC structures. They have predicted the piezoelectric and dielectric properties of GNC using analytical and numerical models. They showed the significant enhancement in static, dynamic and electric response of GNC structures due to incorporation of these size dependent properties. Garcia-Macias et al. [15] also shown GNPs in the composite are superior to carbon nanotubes (CNTs) while considering the load-bearing capacity and stiffening effects. Naskar and co-authors [16]–[19] proposed a new micromechanical analysis for predicting the effective properties of fiber-reinforced composite and functionally graded material (FGM) by using a novel approach of stochastic representative volume element (SRVE) considering spatial distribution with stochastic analysis and uncertainty quantifications. They have also carried out static and dynamic characteristics including sensitivity and frequency analysis of laminated composite and FGM by using a probabilistic uncertainty quantification approach.

Liu and Rajapakse [20] integrated the effect of surface parameters for determining the deflection and vibration of nanoplate. To the authors' knowledge, a flexible piezoelectric graphene-based nanoplate with consideration of effect of flexoelectricity offers various opportunities for developing NEMS. Therefore, in the present study, we develop an analytical model based on Navier's method and Kirchhoff's plate theory for SS nanoplates with considering the effects of flexoelectricity. Obviously, a closed-form solution is developed for nanoplates with uniformly distributed loading (UDL) was evidently absent from the earlier literature.

GOVERNING EQUATIONS FOR PIEZOELECTRIC PLATE

In this, the governing equations for graphene-reinforced composite (GRC) plate subjected to the uniformly distributed mechanical load (q_0) are derived from investigating its static bending and dynamic behavior considering the flexoelectric effect. **Fig. 1** shows the schematic of simply-supported (SS) GRC nanoplate having thickness h , length a and width b . A Cartesian coordinate system is used to describe the nanoplate with a thickness along the z -axis and the midplane of the unperformed nanoplate that coincides with the x - y plane.

Fig. 1: Representation of a SS GRC nanoplate under UDL

Assumptions of Kirchhoff's Plate Theory

- Straight lines normal to the mid-surface (i.e., transverse normals) before deformation remain straight after deformation.
- The transverse normals are inextensible (i.e., do not experience elongation).
- The thickness of the plate does not change during deformation.
- The transverse normals rotate such that they remain normal to the middle surface after deformation. The first three assumptions signify that transverse displacement is independent of transverse (or thickness) coordinate and transverse normal strain is zero. The last assumption indicates zero transverse shear strain.

As per Kirchhoff's plate theory, the in-plane displacement of the plate in terms of transverse displacement $w(x,y,t)$ can be expressed as [21]:

$$u(x, y, z, t) = -z \frac{\partial w(x, y, t)}{\partial x};$$

$$v(x, y, z, t) = -z \frac{\partial w(x, y, t)}{\partial y};$$

$$w(x, y, z, t) = w(x, y, t) \tag{1}$$

where u and v are displacement components with respect to x and y directions, and t is the time. Considering the infinitesimal deformation, by assuming the coupling between electric field and strain gradient, the constitutive Eq. for the energy density function U is expressed as [22]:

$$U = -\frac{1}{2} \epsilon_{kl} E_k E_l + \frac{1}{2} C_{ijkl} \epsilon_{ij} \epsilon_{kl} - e_{ijk} \epsilon_{ij} E_k - \mu_{ijkl} E_i \eta_{jkl} + r_{ijklm} \epsilon_{ij} \eta_{klm} + \frac{1}{2} g_{ijklmn} \eta_{ijk} \eta_{lmn} \tag{2}$$

in which, ϵ_{kl} , C_{ijkl} , e_{ijk} , μ_{ijkl} denote the permittivity, elastic, piezoelectric, and flexoelectric coefficient, respectively; ϵ_{ij} , E_i , and

η_{jkl} indicate the component of strain, electric field, and the strain gradient, respectively; r_{ijklm} are the coupling amongst the strain and strain gradient and g_{ijklmn} are the components of nonlocal elastic effects which are neglected for simplicity. Here, for convenience, we consider the flexoelectric coefficient can be presented such as $\mu_{31} = \mu_{3113} = \mu_{3223}$ [23]. Using the equation of Gauss' law of electrostatics ($\nabla \cdot D = \rho_s$), in the absence of free electric charge (ρ_s), the electric displacement for the thin nanoplate can be written as:

$$\frac{\partial D_z}{\partial z} = 0 \tag{3}$$

The governing equations for the SS nanoplate problem can be derived using dynamic version of Hamilton's variational principle, such as [24]:

$$\delta \int_0^t (U + W - K) dt = 0, \tag{4}$$

Boundary conditions considered for SS rectangular GRC nanoplate on all four edges are prescribed and can be deduced as [24]:

at $x = 0$ and $x = a$:

$$w = 0, M_{xx} = 0. \tag{5}$$

at $y = 0$ and $y = b$:

$$w = 0, M_{yy} = 0. \tag{6}$$

By virtue of Eqs. (5-6): M_{xx} , M_{xy} , M_{yx} and M_{yy} indicate the bending moments, N_{xxz} and N_{yyz} are the axial force across the thickness and is presented as:

$$\begin{aligned} M_{xx} &= \int_{-\frac{h}{2}}^{\frac{h}{2}} \sigma_{xx} z dz, & M_{yy} &= \int_{-\frac{h}{2}}^{\frac{h}{2}} \sigma_{yy} z dz, \\ M_{xy} &= M_{yx} = \int_{-\frac{h}{2}}^{\frac{h}{2}} \tau_{xy} z dz \end{aligned} \tag{7}$$

$$N_{xxz} = \int_{-\frac{h}{2}}^{\frac{h}{2}} \tau_{xxz} dz, \quad N_{yyz} = \int_{-\frac{h}{2}}^{\frac{h}{2}} \tau_{yyz} dz \tag{8}$$

By using values of M_{xx} , M_{xy} , M_{yx} , M_{yy} , N_{xxz} and N_{yyz} into Eq. (5 and 6), the governing expression for the transverse deflection w is given as:

$$\begin{aligned} F_{11} \left(\frac{\partial^4 w}{\partial x^4} + \frac{\partial^4 w}{\partial y^4} \right) + 2(F_{12} + 2F_{66}) \frac{\partial^4 w}{\partial x^2 \partial y^2} + \\ \rho h \frac{\partial^2 w}{\partial t^2} = q_0 \end{aligned} \tag{9}$$

with

$$\begin{cases} F_{11} = \left(C_{11} + \frac{e_{31}^2}{\epsilon_{33}} \right) \frac{h^3}{12} + \frac{\mu_{31}^2}{\epsilon_{33}} h \\ F_{12} = \left(C_{12} + \frac{e_{31}^2}{\epsilon_{33}} \right) \frac{h^3}{12} + \frac{\mu_{31}^2}{\epsilon_{33}} h \\ F_{66} = C_{66} \frac{h^3}{12} \end{cases} \tag{10}$$

It can be concluded that bending stiffness of the GRC nanoplates is influenced by flexoelectricity i.e., in case of F_{11} and F_{12} it will increase but will not change in case of F_{66} . From the above formulation, it is observed that the flexoelectric effect has a significant influence on the bending stiffness of nanoplate.

Derivation for Static Response

The governing equation (9) in terms of static mechanical bending behavior of the GRC nanoplates can be re-expressed as:

$$F_{11} \left(\frac{\partial^4 w}{\partial x^4} + \frac{\partial^4 w}{\partial y^4} \right) + 2(F_{12} + 2F_{66}) \frac{\partial^4 w}{\partial x^2 \partial y^2} = q_0 \tag{11}$$

It should be revealed that in the absence of the flexoelectric effect, considering linear piezoelectricity, the above governing equation can follow the conservative Kirchhoff plate theory. Hence, to derive the governing Eq. (11) of the SS GRC plate, the Fourier series is expressed for $w = w(x,y)$ are as follows:

$$w(x,y) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} A_{mn} \sin \alpha x \sin \beta y \tag{12}$$

where $\alpha = \frac{m\pi}{a}$, $\beta = \frac{n\pi}{b}$ and A_{mn} are the coefficients to be evaluated for each m and n should be satisfied everywhere in the domain of the plate. By making use of Fourier series, the uniformly distributed load $q_0(x,y)$ is expressed as:

$$q_0(x,y) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} Q_{mn} \sin \alpha x \sin \beta y \text{ and } w(x,y) = \frac{Q_{mn}}{d_{mn}} \tag{13}$$

where

$$Q_{mn} = \frac{16q_0}{mn\pi^2} \quad m, n = 1, 3, 5, \dots$$

$$d_{mn} = \tag{14}$$

$$\left(\frac{\pi}{b} \right)^4 \left\{ F_{11} \left(\frac{m}{a} \right)^4 + F_{12} \left(\frac{n}{b} \right)^4 + 2(F_{12} + 2F_{66}) \left(\frac{mn}{ab} \right)^2 \right\} \tag{15}$$

By putting Eqs. (14 and 15) into Eq. (13), to derive transverse deflection, one can acquire the solution for the SS plate.

Numerical outcomes validate that the transverse deflection series has a quick convergence rate, and the first term with respect to $m = 1$ and $n = 1$ is far higher compared to the other factor. Thus, taking the first term from the above equation, one can derive the approximate solution.

Derivation for Dynamic Response

The dynamic behavior of GRC nanoplates can be expressed by using Eq. (10) as follows:

$$F_{11} \left(\frac{\partial^4 w}{\partial x^4} + \frac{\partial^4 w}{\partial y^4} \right) + 2(F_{12} + 2F_{66}) \frac{\partial^4 w}{\partial x^2 \partial y^2} + \rho h \frac{\partial^2 w}{\partial t^2} = 0 \tag{16}$$

Analogous to the conservative model for plate, the periodic solution for $w(x,y,t)$ is obtained as:

$$w(x,y,t) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{mn} \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b} e^{i\omega_{mn}t} \tag{17}$$

in which B_{mn} , m , n and ω_{mn} represent the mode shape amplitude, the half wave numbers, the resonant frequency, respectively, and $i_2 = -1$.

Substituting Eq. (17) into Eq. (16), the plate resonant frequency written as follows:

$$D_{11} \left[\left(\frac{m\pi}{a} \right)^4 + \left(\frac{n\pi}{b} \right)^4 \right] + 2(F_{12} + 2D_{66}) \left(\frac{m\pi}{a} \right)^2 \left(\frac{n\pi}{b} \right)^2 - \rho h \omega_{mn}^2 = 0 \tag{18}$$

From above, it is clear that if flexoelectric effects are neglected, then the resonant frequency will be evaluated through the

conservative theory of piezoelectricity. In this study, we only consider the mode (1,1) resonant frequency ω_{11} (i.e., fundamental frequency) with a variation of aspect ratio and thickness of the plate in the subsequent section.

RESULTS AND DISCUSSIONS

In this section, to examine the influence of size-dependent properties on the static and dynamic behavior of GRC nanoplates, we considered the effective properties of GRC accounting the graphene volume fraction as 10% and are summarized in **Table 1**.

Table 1: Effective properties of GRC

Material	C_{11} (GPa)	C_{12} (GPa)	C_{66} (GPa)	e_{31} (C/m ²)	ϵ_{33} (10 ⁻¹¹ F/m)
Graphene	9.99	6.66	1.67	-0.0002	3.815

The density of the GRC, ρ_{nc} , graphene, ρ_g , and polyimide, ρ_m is 1417 kg/m³, 2200 kg/m³ and 1330 kg/m³, respectively. The uniformly distributed load is considered as $q_0 = 0.05$ MPa. Zubko et al. [25] confirmed by using the experimental methods and to more specific, it is experimentally validated for polymers that the flexoelectric coefficient is ranges from (10⁻⁸–10⁻⁹ C/m). Henceforth, we assumed the flexoelectric coefficient $\mu_{31} \approx 10^{-8}$ C/m for our calculations.

Static and Dynamic Response

Figs. 2 and 3 represent the maximum deflection of GRC nanoplates with and without flexoelectricity effect and the normalized maximum deflection (i.e. w/w_0) of the nanoplate against the thickness of the plate at the fixed in-plane dimension ($a=b=45h$ and $55h$). It can be seen from figure 2 that the flexoelectric effect is size-dependent, i.e., the smaller the plate’s thickness better the result. Where w and w_0 is a maximum deflection of the GRC plate with and without considering the flexoelectricity effect, respectively. It is obvious that the consideration of influence of flexoelectricity results in the lower deflection of a GRC nanoplates over that of classical plates.

As expected, from figure 3, it may be concluded that the influence of the flexoelectric effect is most effective for smaller thickness, it becomes negligible when the plate thickness increases. Figs. 4 and 5 illustrate the influence of size-dependent characteristics on the dynamic behavior of piezoelectric GRC plates for the resonant frequency and the normalized fundamental frequency of mode (1,1), respectively, against the corresponding thickness.

From **Fig. 4**, it can be determined that as the plate thickness is smaller (< 30 nm), the resonant frequency is lower for the plate without flexoelectric effect as that of the flexoelectric nanoplate. Also, it may be seen that the resonant frequency is dependent on the dimension of the plate, as the in-plane dimension increases the resonant frequency diminishes. The resonant frequency ratio ($\omega_{mn} / \omega_{mn}^0$) is the ratio of frequency of flexoelectric SS plate ω_{mn} and conventional plate ω_{mn}^0 . From **Fig. 5**, it can be concluded that the results for the ratio of resonant frequency diminishes progressively as the plate thickness increases, and it lastly reaches unity for both cases considering in-plane dimension ($a = b = 45h$ and $55h$). Concisely, the effect of size-dependent properties becomes more pronounced as the plate thickness decreases. The ratio of resonant frequency is near about ~5.5 times the frequency without considering flexoelectricity.

Fig. 5: Resonant frequency ratio against the thickness of plate

CONCLUSIONS

In this novel work, the flexoelectric plate model based on the Navier’s method and Kirchhoff’s plate theory are developed to explore the static and dynamic behavior of simply supported GRC plates including the deflection and frequency analysis. The numerical outcomes reveal the influence of effect of flexoelectricity on the static and dynamic behavior of GRC nanoplates is significant for nanoplates with a smaller thickness while the influence diminishes with the rise of the plate thickness. The current study might provoke the investigators to build this novel GRC and aid the purpose of validating the experimental approximations. We expect that some of the enhancements outlined in the current work will guide the pathway for exploring the different structural health monitoring and energy harvester in NEMS application.

ABSTRACT

In this paper, the ground effects on a two-dimensional flapping elliptic airfoil is investigated at three different pivot locations. The numerical simulations are conducted using a finite volume solver at a fixed Reynolds number of 5000. Five different ground clearances between $1c$ to $5c$ are considered to investigate the transient and time-averaged aerodynamic force performance of the flapping airfoil. Here, c is the chord length of the airfoil. We found that the thrust and lift performance of the airfoil is significantly enhanced when the ground clearance is less than $2c$; otherwise, their variations are minimal. Additionally, we have observed that the pivot location near the trailing edge produces a better thrust force than the other two pivot locations at least in the considered parametric space. However, when it comes to the lift force the center pivot location shows a better performance.

Keywords : Flapping elliptic airfoil; Pivot point location; Ground effect; Low Reynolds number; Ansys-Fluent.

INTRODUCTION

In the last few decades, the use of flapping wing-based propulsion mechanism in the Unmanned Under Water Vehicles (UUWVs) and Micro Aerial Vehicles (MAVs) has gained popularity since it produces better manoeuvrability compared to the fixed and rotary wing type propellers (Platzer et al. [1]). Often these UUWVs operate near the ground or shallow water environments. Previously, researchers have tried to understand the wing in the ground effect (WIG). However, they mainly considered conventional fixed-wing or airfoil configurations (Wu et al. [2]). Note that the analysis of the fixed-wing in WIG configuration may not be applicable for the corresponding flapping-wing cases since in the latter the unsteady wake dynamics are more pronounced. Nevertheless, the benefits of fixed-wing in WIG configuration have been already explored in WIG crafts, race cars, etc (Qu et al. [3]). Whereas the studies and engineering applications involving flapping wing in WIG configuration is still in the budding phase. In the following, we have reviewed some of the relevant studies with the flapping wing in WIG configuration.

Liang et al. [4] have performed analytical studies on a sinusoidal heaving of NACA 0012 airfoil over a flat and wavy surface. They have found that for a particular reduced frequency the time-averaged lift coefficient is enhanced when the gap ratio between the airfoil and ground surface is decreased. A similar study was done by Wu and Zhao [5] using the immersed boundary-lattice Boltzmann method (IB-LBM) for the heaving of NACA0012 airfoil near the ground surface. They have observed that the critical Strouhal number (or the non-dimensional flapping frequency) to be around 0.3 to generate thrust or positive lift for the airfoil heaving near the ground. Additionally, they have reported for higher flapping frequency and smaller ground clearance distance, the magnitude of generated lift and thrust force gets enhanced. Ahmed and Sharma [6] and Luo and Chen [7] have experimentally investigated the effect of varied angle of attack (AOA) and ground clearance. They have observed that at close proximity to the ground, a high-pressure region is formed on the bottom surface of the airfoil which favours the extra lift and thrust force generation. This phenomenon is otherwise known as the “Ramming Effect” or “Convergent-Divergent Channel Effect”. Furthermore, they noticed the pressure distribution on the upper surface of the airfoil is more dependent on the AOA than the ground clearance whereas the pressure variation on the lower surface of the airfoil is equally dependent on both. A similar observation was reported by Qu et al. [3]. In another study, Wu et al. [8] have investigated the ground effect on the energy harvesting aspect of the flapping NACA 0015 airfoil using IB-LBM simulations. They have reported that superior power extraction efficiency can be achieved in the case of low ground clearances. A similar observation was postulated by Wu et al. [9] when the flat ground was replaced by a wavy ground. Furthermore, Wu et al. [10] have conducted numerical simulations to determine the scope of the power extraction of the flapping wings between the two parallel walls or grounds. At low $Re = 150$, using IB-LBM simulations Wu et al. [2] have investigated flapping of NACA 0012 airfoil with varied ground clearances and flapping frequency (or St). They found that close to ground drag coefficient increases whereas the lift coefficient reduces.

Also, they have further observed that at high Strouhal numbers, the shed vortices and ground induced vortices interact with each other and propagate obliquely in the wake. Mivehchi et al. [11] have performed experiments in a towing tank on high aspect ratio flapping airfoil and showed that the flapping kinematics can be adjusted to capture the positive effect of ground without sacrificing thrust. Apart from the symmetric flapping cases, Lin et al. [12] have investigated flapping airfoil with asymmetric heaving motion. They found the thrust coefficient increases when the duration of upstroke is reduced and the lift coefficient increases when the duration of down stroke is reduced.

We noticed that the above-cited flapping wing in WIG configurations studies are limited to a particular pivot location on the flapping airfoil. Therefore they fail to explain the significance of pivot-point locations on the flow physics of the near wake region, and transient and time-averaged thrust and lift performance of the flapping airfoil in close proximity to the ground. To bridge the knowledge gap, in this study, we have performed a systematic numerical investigation of the two-dimensional flapping elliptic airfoil. Three different pivot locations on the airfoil are considered. Furthermore, we have assessed the effect of the ground clearance on the aerodynamic performance of the flapping airfoil at five different mean heights of the airfoil from the ground.

METHODOLOGY

Problem Statement

The down stroke and upstroke motion of a flapping elliptic airfoil near the ground is depicted in **Fig. 1(b)**. The sinusoidal heaving $h(t)$ and pitching $\theta(t)$ motion profiles follow the (1) and (2). Here, the phase angle (ϕ) difference between heaving and pitching profile is considered as 90° since at this phase angle generally maximum propulsive efficiency is obtained for the flapping airfoils (Sinha et al. [13]; Anderson et al. [14]).

$$h(t) = h_0 \cos(\omega t) \tag{1}$$

$$\theta(t) = h_0 \cos(\omega t - \phi) \tag{2}$$

$$\alpha(t) = \arctan\left(\frac{h'(t)}{U_\infty}\right) - \theta(t) \tag{3}$$

$$\theta_0 = \left(\frac{\omega h_0}{U_\infty}\right) - \alpha_0 \tag{4}$$

In the present study, the induced geometric effective angle of attack profile $\alpha(t)$ is expressed in (3) where U_∞ is the incoming free stream flow ($U_\infty = 0.125$ m/s). To obtain the pitching amplitude θ_0 , for a fixed maximum amplitude (α_0) of $\alpha(t)$, two scenarios are evaluated. For the low flapping frequency ($St < 0.2$), (4) is used which is a linearized approximated form of (3). For $St \geq 0.2$, the maxima of (3) are used to calculate θ_0 . Here, $h_0 = 0.75c$ and $\alpha_0 = 10^\circ$ are the heaving and effective angle of attack amplitude, respectively and $c = 0.04$ m is the chord length of the flapping airfoil. h_m is the mean distance of the airfoil from the ground which is varied from $1c$ to $5c$ at an interval of $1c$. f and ω is the flapping frequency and angular flapping frequency, respectively. Moreover, to investigate the thrust performance of the flapping airfoil, three pivot points A, B and C at locations $0.25c$, $0.5c$ and $0.75c$ from the leading-edge are considered, respectively, as shown in **Fig. 1(b)**. Additionally, for the present analysis, two non-dimensional numbers, Reynolds number, $Re = U_\infty c/\nu$ and Strouhal number $St = fA/U_\infty$ are defined. Here, ν is the kinematic viscosity of the fluid and A is the width of the wake (= maximum excursion of the trailing edge of the airfoil, i.e. $2h_0$). The transient thrust and lift coefficient is defined using a generic force coefficient expression, $CF = \left(\frac{F}{0.5\rho U_\infty^2 S}\right)$, where F can be thrust or lift force, ρ is the density of the fluid and $S=1.0$ is the planform area of the airfoil.

Numerical Solver Details

In the present study, a finite volume method (FVM) based commercial software package, ANSYS FLUENT

is utilised to simulate the transient incompressible flow over a flapping elliptic airfoil at $Re = 5000$ and $St = 0.3$ with a laminar viscous flow model. The effectiveness of the ANSYS FLUENT solver in simulating flapping airfoil problems has been thoroughly verified and documented in the literature (Dash et al. [15]). Using the dynamic mesh principle, the conservative form of the governing equations shown in (5) is solved in an inertial frame of reference on an arbitrary control volume cv with moving control surface cs .

$$\frac{\partial}{\partial t} \int_{cv} \rho \psi dV + \oint_{cs} \rho n \cdot (v - v_g) \psi dS - \oint_{cs} \rho \Gamma_\psi n \cdot \nabla \psi dS = \int_{cv} S_\psi(\psi) dV \tag{5}$$

Here, the variables v , v_g , Γ_ψ , S_ψ , and ρ , are the flow velocity, moving mesh velocity, diffusion coefficient, source term of ψ per unit volume and fluid density, respectively. n is the unit vector normal to the control surface. Pressure and velocity coupling are done using the Pressure-Implicit with Splitting Operators (PISO) algorithm. We have used the PISO skewness correction for highly-distorted meshes and the under-relaxation factors for the momentum and pressure are defined as 0.3 and 0.7, respectively. Spatial and temporal discretization of the momentum equation is carried out using the second-order upwind scheme and first-order implicit scheme, respectively. A double-precision solver setting is followed to approximate the computer-generated round off errors. The convergence criterion for the iterative method for both momentum and mass residuals are kept to $O(10^{-5})$.

Computational Domain, Mesh and Validation

A semicircle type computational domain as shown in Fig. 1(a) is adopted in the present simulations. The domain is subdivided into three zones with a deforming inner zone Ω_2 and a stationary outer zone Ω_3 . Ω_1 is moved as a rigid body along with the airfoil wall (Γ_0). Between the two zones Ω_2 and Ω_3 , an interior boundary condition (Γ_1 and Γ_2) is applied. The inner (Γ_2) and outer (Γ_3) boundaries are located at a radius of $15c$ and $30c$, respectively, so that the far-field boundary effects on the airfoil wall are negligible. At the start of the flapping stroke, the center of the elliptic airfoil is located at a distance of H ($H = h_m + h_0$) from the ground wall. On the inlet section, a uniform free-stream velocity (U_∞) in the X-direction is assigned. No-slip velocity condition on the airfoil wall and solid ground (Γ_4) is implemented. Atmospheric pressure condition on the outlet boundary is applied. Standard initialization is adopted for computing the result from the inlet. To obtain the flapping motion profile shown in (1) and (2), a C-programming based user-defined function (UDF) is written and compiled in ANSYS FLUENT.

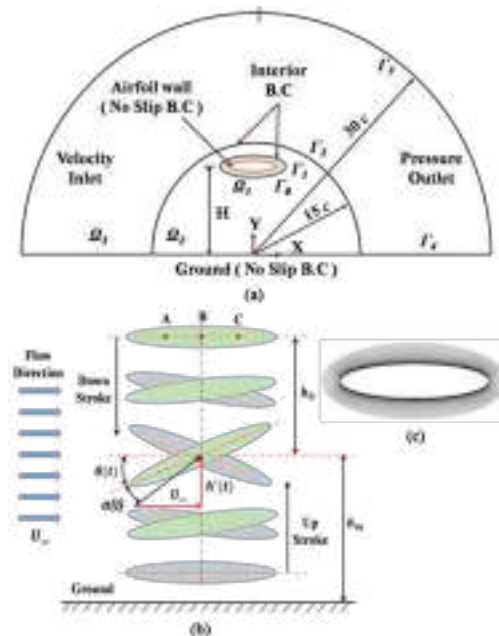

Fig. 1: (a) Represents the semicircle type computational domain and (b) shows the flapping cycle of the elliptic airfoil near the ground. The pivot points A, B and C on the airfoil are located at a distance of $0.25c$, $0.5c$, and $0.75c$, from the leading-edge, respectively. (c) close up view of the mesh around the elliptic airfoil which will move as a rigid body along with the airfoil.

Grid Independency Test and Validation

A structured mesh with quadrilateral elements has been generated in the computational domain using face meshing. A close-up view of the mesh around the airfoil is shown in **Fig. 1(c)**. Here, keeping the outer domain stationary, diffusion smoothing based dynamic mesh technique was incorporated only in the inner zone to minimize computational time. To perform the grid independence study, five different mesh sizes as shown in **Table 1** are selected. Since for the mesh size M3, the error percentage of time-average CT is below 0.1%, therefore it is chosen for the rest of the simulations. Additionally, we have validated the numerical solver by performing a simulation similar to that of Wu et al. [8] and compared the time-averaged CL (refer **Fig. 2**). The results obtained in the present solver are found to match excellently.

Table 1: Grid independency test

Grid name	No of nodes	CT value	$\% \text{Error} \left \frac{C_{Tnew} - C_{Told}}{C_{Told}} \right \times$
M5	93,422	0.2409	0.3320
M4	81,422	0.2401	0.1249
M3	69,422	0.2398	0.0834
M2	57,422	0.2396	0.0417
M1	45,422	0.2395	-

Fig. 2: Comparison of time-averaged CL values obtained in the present solver with that of the Wu et al. [8]

RESULT AND DISCUSSION

In **Fig. 3**, the numerical results of the time-averaged thrust and lift coefficient as functions of ground clearance (h_m/c) are plotted at three different pivot locations of the flapping airfoil. Notice in **Fig. 3** that at all pivot locations, with decreasing ground clearance, a negligible amount of increment in time-averaged C_T is observed till $h_m/c = 2$. On the other hand when $h_m/c < 2$, a substantial enhancement of the time-averaged C_T is observed. A similar trend is also found for the time-averaged C_L . Furthermore, between the pivot locations, pivot A and C are found to have superior thrust performance compare to pivot B irrespective of ground clearance. But in the matter of lift, generally, the pivot locations near the leading (pivot A) and trailing (pivot C) edge under perform than that of the center pivot location (pivot B). It is worth highlighting here that at a sufficiently large ground clearance, both time-averaged thrust and lift coefficients attain a value same as that of the infinite domain case (i.e. in absence of ground effect).

To better understand the time-averaged C_T and C_L variation at different pivot locations of the flapping airfoil we have further investigated the transient C_T and C_L profile over one flapping cycle for only one representative case of $h_m/c = 1$ at three pivot locations. It is noticed that the transient C_T and C_L plots distinctively vary at different pivot locations (compare in **Fig. 4**) and

their trends were asymmetric between the two flapping strokes (i.e. upstroke and down stroke).

Fig. 3: Shows the numerically obtained time-averaged CT and CL values at three different pivot locations (namely A, B and C) with varied ground clearances

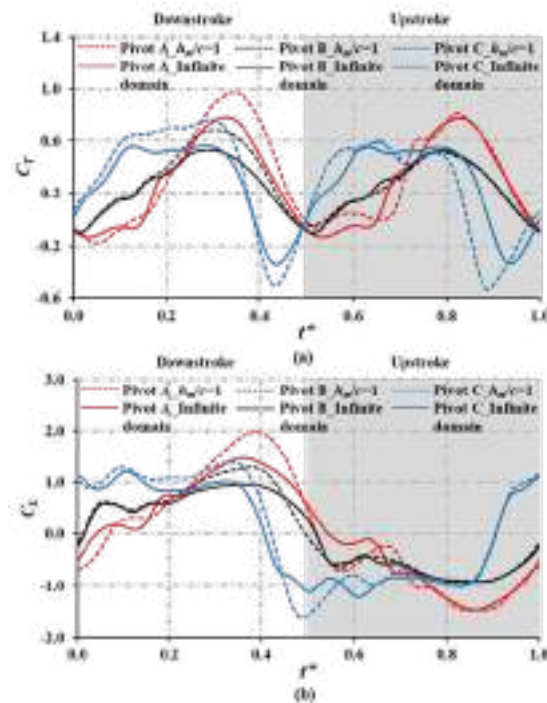

Fig. 4: Shows the comparison between numerically obtained transient (a) C_T and (b) C_L for $h_m/c = 1$ and infinite domain case for pivot A, pivot B and pivot C

Moreover, higher transient C_T and C_L peaks are observed in the case of downstroke i.e. when the airfoil is moving towards the ground. This improved aerodynamic performance in the downstroke is because of the ramming effect (Luo & Chen [7]) in which a favourable high-pressure region is formed between the airfoil and ground (see in **Fig. 5**). In general, the transient force profiles follow a parabolic pattern. Here, due to page limitations, the details of the flow physics associated with different types of transient C_T and C_L profiles are not discussed which can be found elsewhere (Sinha et al. [16]). Further notice that between three pivot locations the transient C_T peak is found to be lower for pivot B, which may have led to reducing time-averaged thrust performance compare to pivot A and C cases. However, when it comes to the lift performance pivot B attains a higher region of the transient C_L with a positive value than pivot A and C that may have attributed to its greater time-averaged lift performance. Additionally, in **Fig. 4**, we have compared the transient C_T and C_L values for the infinite domain case. It can be clearly seen in **Fig. 4** that the favourable aerodynamic effects have produced improved transient C_T and C_L performance in the presence of ground.

Fig. 5: Depicts the favourable high-pressure region under the airfoil due to the ramming effect

CONCLUSION

In the present numerical study, the effect of solid ground on a two-dimensional flapping elliptic airfoil is investigated at three different pivot locations for Reynolds number of 5000, $St = 0.3$ and $\alpha_0 = 10^\circ$. Five different ground clearances between $1c$ to $5c$ are considered at an interval of $1c$. Here, only the transient and time-averaged aerodynamic force coefficients are evaluated. We observed that the thrust and lift performance of the airfoil is enhanced when the ground clearances less than $2c$. This is because of the formation of the high-pressure region around the airfoil due to the ramming effect. Additionally, we have observed that in terms of the thrust performance, the pivot location near to trailing edge (i.e pivot C) performs better than other pivot locations at least for the range of parameters investigated here. Whereas the center pivot location (i.e pivot B) shows a better lift performance.

ABSTRACT

Economic needs as well as ecological demands are major driving forces in improving the chemical processes and developing of alternative or secondary resources. Oceans contain around eighty elements of periodic table and some of the elements are very scarce on land and/or very expensive, elements such as uranium, vanadium are also a few among them. With its lean but clean resource, oceans can serve as constant potential source of valuable technology elements for a long run. India with a large coastline has a large stake in exploiting the valuable elements locked in seawater. The greatest of the scientific and technological challenges in extracting technology metals from seawater are lying in finding a technology that gives a net positive energy balance in terms of electricity produced from the so recovered uranium and the other is the cost of production. The Indian efforts in addressing these issues and pilot scale demonstrations based on lab-scale field trials being carried out are presented in this paper.

Keywords : Oceans; Radiation processing; Tidal energy; technology metals; Secondary sources.

INTRODUCTION

With merits of high energy density and nearly zero greenhouse gas's emissions, the nuclear power serves as an important energy resource worldwide. To this day, uranium is the major ingredient for the most nuclear power stations. The booming growth in the demand of the nuclear energy is stimulating exploitation of uranium ores. The process of mining, metallurgy, and especially in situ leaching and disposing tailing of uranium ore often releases uranium nuclides in the formation of uranyl into the aqueous environment. Furthermore, due to incredibly diffuse electrons in 5f orbital the element uranium is prone to coordinate with various ligands containing electron-donor atoms such as nitrogen, phosphorus, sulfur and oxygen etc. through coordination bonds. It is such coordination interaction that makes uranium highly mobile in aqueous environments. Literature and publications point out the large resources of valuable elements in the world's oceans with remarkably uniform concentrations [1, 2, and 3]. In addition, 8500 tonnes per year enter the oceans through rivers and submarine eruptions [4, 5]. Oceans contain around eighty elements of periodic table and some of the elements are very scarce on land and/or very expensive, uranium and vanadium are also few elements among them with relative abundance factors of 23 & 24 respectively. Uranium subsists in the environment due to leaching from mine tailings, natural deposits, use of uranium-containing phosphate fertilizers, emissions from the nuclear industry. With its lean but clean resource, oceans can serve as constant potential source of uranium and other valuable elements for a long run. Based on an average seawater salt content of about 3.5%, the salt concentration is 106 – 107 times larger than the concentrations of trace elements like U, V, Fe, Ni, Cu, Zn, Li and Au. In the last century uranium has universally gained acceptance as primary energy source. Currently it caters to ~17% of the electricity generation globally. Uranium has been projected as the main workhorse of future when the fossil energy reserves dwindle by the middle of this century. The terrestrial distribution of uranium ore occurrence is grossly uneven. With a large coastline, India, Japan, Korea and a few other nations have a larger stake in exploiting the 4.5 billion tonnes of uranium locked in seawater [4, 5 and 7]. Also the electricity produced from nuclear energy with uranium extracted from oceans has the advantage of No mill tailings; No fly ash and No carbon dioxide generation. The recovery of valuables from seawater requires the processing of large amounts of water, depending on the efficiency of adsorption and elution processes. The problems to be addressed as a part of R&D activities are to develop most effective and most selective extraction system and associated chemical engineering and to develop economic method of contacting large amounts of water with such extraction system. The uranium concentration in various secondary sources and corresponding reserves are as given in following **Table 1**.

Uranium bearing substances	Avg. Concentration (mg/L)	Reserves (10 ⁶ tU)
Conventional uranium ores	350-5000 and more	4-5
Phosphates	100-200	5-10

Bauxite	8-12	0.09-0.1
Lignite	0.1-1	0.15-1.5
Granite	4	4×10^3
Manganese modules	4-7	10-14
Shelf sediments	1-4	$3-4 \times 10^5$
Seawater	0.003	4.5×10^3

The granite source containing 4 ppm of U concentration with total reserves of 4 billion tones has the drawback being in solid form and technology demonstration is not available. But in case of seawater, the uranium is present in ionic form in liquid phase and which is easier to process with the technology being developed. This article deals with the Indian efforts on these issues and highlighting the demonstration of pilot scale “RUSWapp~100g “facility. Also large quantity of seawater being pumped into the facilities, either for condenser cooling at power plants or for desalination purposes and thus opportunity for co-generation of technology metals.

PROCESS MECHANISM

During seventies and eighties the Initial investigations on the possibilities of recovery of uranium from seawater have been done using inorganic adsorbents [5, 6 and 7]. The inorganic adsorbents suffer limitations of adsorption rate and insufficient mechanical stability. Since early nineties extensive investigations are being carried out on organic adsorbents. Polyacrylo Amid Oxime (PAO) has been picked up as the best bet for our studies. It preferentially extracts heavy metal ions by chelating mechanism [7, 8]. A polypropylene fiber substrate is irradiated with electron beam to create grafting sites on the polymer chain and then treated with acrylonitrile to graft cyano groups on those sites. Then the cyano groups are reacted with hydroxylamine to convert them into amidoxime groups. These amidoxime groups trap the loosely bonded uranyl ion from the uranyl tricarbonate present in the ionic form i.e. $UO_2 (CO_3)_3^{4-}$ in seawater. The adsorption mechanism is given in the Fig. 1.

Fig. 1. Adsorption Mechanism of uranyl ion

Thus for each pair of two molecules of polyacrylo amidoxime (PAO), one uranium atom is captured. Stoichiometrically PAO will have an extraction capability of 3600 g U/kg PAO.

DESCRIPTION OF THE LAB-SCALE EXPERIMENTS

Substrate: During lab-scale experiments, many types of fiber cross-sections and geometries were evaluated for establishing efficacy of grafting. Polypropylene fiber of 1 to 2 Denier cross-sections as stem material in non-woven felt form was used. Electron Beam Radiation induced grafting of acrylonitrile was carried out with optimized parameters [9, 10, and 11]. The solution viscosity and temperature were also found to be important factors. Then the cyano group was converted to PAO as shown in Fig. 2.

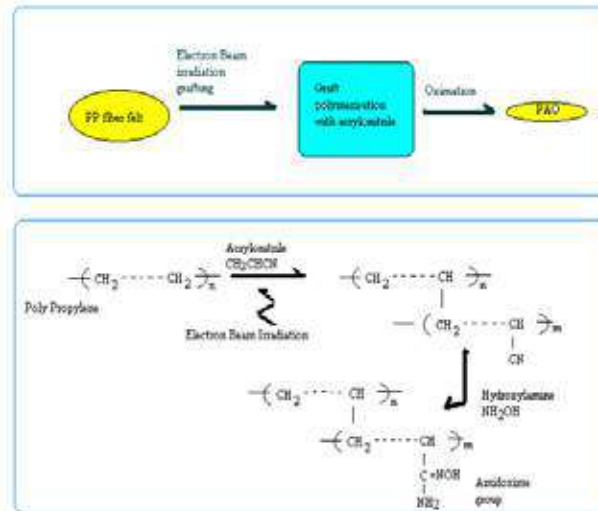

Fig. 2. Cyano group conversion to PAO

The substrate was then reacted with alkaline solution to impart hydrophylicity and adsorption characteristics. The tokens of size 75x75x2 mm thick and 150x150x2 mm thick were used in the lab scale field trials.

Experimental results: The summary of the experimental results in terms of concentration factors evaluated for different field trials conducted at various sites is shown in **Table 2**. Corrosion, bio fouling and their combined effect on the adsorption kinetics and mechanical properties of the materials used in the suspension assembly and the substrate were studied. Their compatibilities with seawater and process chemicals were established. The optimum submergence periods for various locations were also studied. The liquid samples are analysed using advanced nuclear analytical technique for estimating lean concentrations of technology metals [12].

Table 2. Summary of the lab scale experimental results

Sl. no	Location	Concentration Factors achieved		Remarks
		Uranium	Vanadium	
1	CIRUS jetty Trombay	300	200	For submergence period of 12 days
2	NPP Intake/Out fall canals Tarapur	600	500	For submergence period of 14 days
3	Andoman & Nicobar Islands	700	Not analysed	For submergence period of 23 days

Process flow sheet for 100gU/year semi pilot scale facility

Based on initial success of extracting micro grams and milligrams of uranium at lab scale by harnessing the tidal wave using PAO adsorbent, a process flow sheet for a facility to extract 100gU/year has been developed. Compared to lab scale, a surface area scale up factor of 1200 has been maintained in pilot scale facility. The process flow sheet of RUSWapp~100g facility was evolved, designed, installed and commissioned at Trombay for demonstration trials. The process block diagram is as shown in **Fig. 3** below. The holdup volumes of process reactors are 2000 litres and 2 bar steam is used as heating medium. The required mixing and turbulence is maintained in the process using continuous recirculation of the solution mixture. The adsorbent is used in the form of leaflets of size 1mx1mx1m with 27 of sheets per contactor assembly and a gap of 30 mm is maintained between the sheets for achieving optimal hydrodynamics. The material of construction for contactor assembly is polypropylene, which is compatible for both hot alkali and acid solutions. The scaled up facility has given pick up rate of 0.6 g of Uranium per kg of adsorbent material against the reported literature of 1 g of Uranium per kg of PAO for the first A-S-E cycle. The preferential fractional elution for technology metals of interest is demonstrated with this facility.

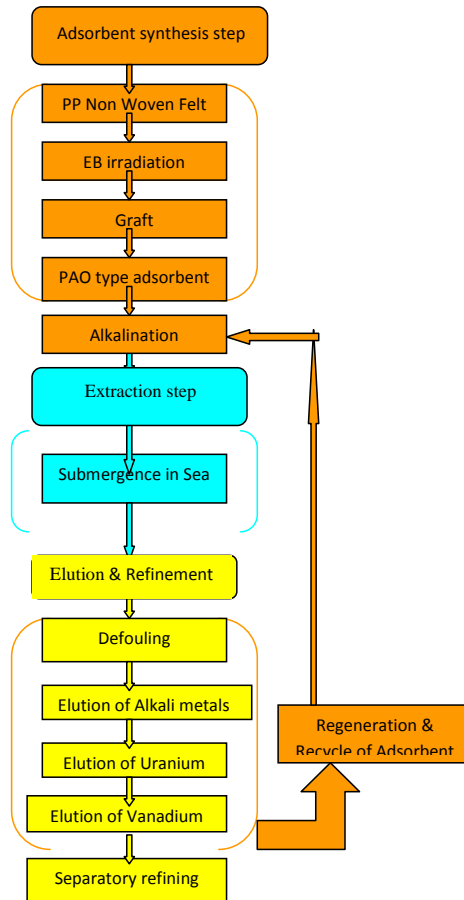

Fig. 3. Block diagram for uranium extraction from

Fig. 4 below shows the details of semi pilot scale RUSWapp~100g facility for the A-S-E (Alkalinization-Submergence-Elution) cycle and arrangements for De-fouling of 1Mx1Mx1M contactor assemblies. Each A-S-E cycle consumes duration of approximately 20 days including defouling time.

Fig. 4. Semi pilot scale RUSWapp~100g facility

The technological scenario assumed for the design is having a global information base as well as the strength of in house experiments. A full gamut of more than 24 inorganic and organic possible adsorbent materials has been screened. The choice has been zeroed on Polyacrylamid Oxime (PAO) adsorbent with a reasonable and achieved performance of 1g of uranium per kg of PAO as reported in literature. Instead of the postulated peak performance of 3.6g of uranium per kg of PAO in laboratory conditions, our report assumes the performance reported by literature as reasonably achievable by us as well. The life of

substrate and adsorbent material is considered as 25 cycles. The plant basically consists of two on-shore units viz. one for synthesis of adsorbent and the other for elution and further processing. The third component is an offshore unit for mooring of seawater contactor assembly carrying adsorbent. The contact technique is based on floating body method utilizing the tidal rise and fall of the seawater level coupled with the large water body movements due to the tidal changes in the seawater levels.

A conceptual process design and cost benefit analysis is carried out for a 100 Te per year 'uranium from seawater' plant. It includes the costs for off shore and on shore civil works, major process equipment and consumption of chemicals, substrates etc. About 18,000 contactor assemblies of size 4m x 4m x 4m will be used with total load of 6050 Tonne of PAO adsorbent. The project land area requirement for the on shore units is approximately 250m x 250m having the plant area of 60m x 120m for PAO synthesis and 150mX120m for elution and allied services. For the offshore segment the area requirement is 500m x 1000m with water depth >20m at lowest tide conditions. The PAO synthesis unit will have a dedicated electron beam irradiator. The estimated capital outlay is Rs. 1226 Crores for fixed capital, Rs. 240 Crores for working capital. The Annual Operating cost is estimated to be Rs. 260 Crores. Direct manpower requirement is ~310 persons at various levels of operation. The cost of production including depreciation works out to around Rs. 27,600/- per kg of product uranium based on the current status of technology. The project implementation period will be 220 weeks. Thus it is likely to be competitive with the current Indian mining costs.

CONCLUSIONS

The recovery of uranium and other technology metals from seawater has been an area of significant interest since at least the early 1950s. Numerous materials have been examined during the nearly 7-decades-long period since then.

- The contactor assembly loaded with specially developed organic adsorbent PAO has shown promising results for recovery of technology metals from seawater.
- Harnessing tidal waves has the advantage of positive electricity gain.
- The extent of energy gain ratio will depend much on the site selection.
- Feasibility studies on various sizes of pilot scales will help in optimization of process design parameters of adsorbent synthesis and improving the yield of recovered heavy metals.
- Various configurations of contactor array designs are being developed to facilitate the operational flexibility for the offshore unit of the plant and utilization of tidal energy/waves more efficiently.
- Further brine mining aspects are being planned to facilitate value addition to desalination plants in future through the concept of CRUDE (Coupling of Recovery of Uranium and other metals from Desalination Effluents).
- These technological developments will open up indigenous secondary sources for the country in meeting up technology metal requirements.

ACKNOWLEDGEMENTS

Special thanks are due to Director Chemical Engg Group, BARC; Head RTDD/BARC; Head Planning Section CIRUS, BARC and NRG, BARC for their technical suggestions, discussions and infrastructure support. Authors would like to thank all the RUSWapp team members and members of 'DAE-Collective Vision 2004' proposals. Thanks to Homi Bhabha National Institute Mumbai for identifying doctoral research area in this programme.

ABSTRACT

This study was undertaken to enhance seed germination as well as minerals contents in Groundnuts. Groundnut seeds were subjected to microwave field treatments. It was found that its germination was sensitive to microwave irradiations. The power level of 60 % i.e. 540 W for 20 sec duration was found best with 100% germination in comparison with 76% germination for untreated. The seed relationship between minerals and power applied along with time of operation was developed using statistical approach. It was observed that due to microwave treatment with 60% power at 20 sec duration significant improvement in minerals. Thus this methods can be adopted for improvement of immunity among whole population to fight against any pandemic situation.

Keywords : Groundnut germination; Microwave field; Regression model; Minerals.

INTRODUCTION

The effect of this electromagnetic treatment on groundnut seed will be more impactful. This non invasive, cheap and eco-friendly process will help the world to get recover from pandemic covid-19 situation. We all are this situation where we should improve our immune system, we should focus on our foods nutritional values to maintain our health. We have to focus on this friendly research which will lead towards sustainable environmental development. Advantages of this electromagnetic treatment as follows, This treatment help to give the protection to plant. It helps to reduce use of more fertilizer and as we said earlier it will ease to store it for more days. Electromagnetic method will help to use for seed disinfection treatment which will improve plants quality and automatically it helps to increase nutritional value of plant. according to health experts, adequate nutrition and hydration are the cornerstones to build a robust immune system and keep infections in this covid era. People who eat a wholesome diet tend to be healthy with a strong immune system and lower risk of chronic disorders and infectious diseases. Hence it is pivotal to eat a varied diet rich in fresh natural produce to get your daily dose of vitamins, minerals, fibre, proteins and antioxidants. So all these vitamins, minerals, fibre, proteins, antioxidants will boost immunity as early as possible if we do effective research on this electromagnetic seed treatment. This will help to recover easily in pandemic situation and will help to tackle it. The right kind of food you eat plays a key role in determining overall well-being and immunity. To combat deadly coronavirus it is important to eat a well-balanced diet that's why this method will be beneficial.

Recently world population has been accelerating its growth rapidly and will greater than nine thousand million in 2050. however it is difficult to obtain farmland due to urbanization. Thus food storage may become serious issue in near future hence there are requirement of bioresearch to improve the harvest efficiency of food plant.

Many researchers are done electromagnetic treatment on seed like cucumber[9], maize[11], tomato[4][11], and soyabean [5] and give positive result in germination seedling growth & enzyme activity also increases as compare to control (untreated seed). So we can select groundnut seed which contain high nutritional value so we can find out there nutritional parameter experimentally.

Microwave radiation is physical method of stimulation are considered as an innovative area of research and we have emerged as magic tool which could improve the yield of crops. When the rational use of agricultural production space is promoted, pre-treatment of seed with physical factor become more important (Phirke et.al., 1996; Pistruszewski, 1993; Podlesny, 2001)[12] The purpose of investigation non availability of quality seed is one of the major drawbacks. In order to enhance the productivity of groundnut, the seed quality can be maintained either by storing in contorted condition or by seed treatment. Storing the seed under controlled condition [12] is a costly affair and hence seed treatment like electric field application need to be practiced for improving viability and vigour of seed before sowing. Pulsed electromagnetic field showed could replace hormones in

vegetative propagation of oregano stimulating rooting process in stem cutting[9] In view of above circumstances the present research was taken to study the effect of electric field application on growth yield and seed quality parameter of groundnut.

MATERIALS AND METHODS

The present investigation entitled “Effect of electric field application on germination and nutritional content and seed quality of groundnut (*Arachis hypogaea* L.) was conducted during kharif 2017-18, season at Post Graduate Institute of Department of Biochemistry, New Arts, Commerce and Science college, Ahmednagar and MPKV, Rahuri, Ahmednagar.

Laboratory Equipment

The equipment viz. microwave oven was utilised from electrical engineering laboratory, Dr. Annashaeb Shinde College of Agricultural Engineering and double door germination chamber, hot air oven, electrical conductivity meter, weighing balance, measuring scale etc were utilized from seed technology research unit. The laminar air flow, incubation room, petridish, forceps, microscope etc. were made available by seed health testing laboratory.

Chemicals

The chemicals required for bio chemical analysis viz, sulphuric acid, potassium sulphate, mercuric oxide, copper sulphate, sodium hydroxide, sodium thiosulphate, boric acid, hydrochloric acid, monobasic potassium phosphate, dibasic potassium phosphate, hydrogen peroxide, EDTA, was made available by Department of Bio Chemistry, New Arts, Commerce and Science College, Ahmednagar. One year old seeds of groundnut (variety Phule Unnati) were obtained from M.P.K.V Rahuri, Maharashtra.

Treatment details

Groundnut seeds were treated with different electrical power intensities for different duration of exposure by microwave which rated total electric power intensity.

Application of electric field treatment

Microwave oven was setup for 3 desired power level 100%, 80%, 60% each for three time 10sec, 20sec, 30sec. respectively seed were treated for combination of each power level and time period.

Treatment Combination

Table 1. Treatment combination electric field intensities to exposure timing respectively seed were treated

Electric field intensities (%)	Exposure timing (sec)
P1- 100 (900w)	T1 - 10
P2- 80 (720w)	T2 - 20
P3 - 60 (540w)	T3 - 30

P = Power, T = Time

The treatment combination take place as follows, P₁T₁, P₁T₂, P₁T₃, P₂T₁, P₂T₂, P₂T₃, P₃T₁, P₃T₂, P₃T₃ Untreated Controlled.

METHODOLOGY

Sample Collection Fresh and One year old ground nut variety, Phule Unnati were obtained from mahatma Phule Krushi Vidyapeeth Rahuri. Ground nut seed were treated with different electric power intensities for different duration of exposure of microwave.

Germination Test

Germination test were carried out immediately after one day of electrostatic field exposure. Seed were sown kept in germinator where the temp. and humidity were controlled as per ISTA standard at 25oc. 80% respectively. Final count was measure on 8th day given in table.

Root shoot Length

Ten normal seedling from each of the replication of germination test were randomly selected and root shoot length was measured

in cm. The average length was calculated and recorded in cm.

Ash and Moisture Content

Sample of 2 gm was used in analysis of ash content ground nut was final grind using grinder before carry out ash analysis sample are high in moisture often dried to prevent spattering during ashing. Muffle furnace was used for determine ash content at the pre ground substance to be examined weighted into inclination tray. The tray is placed into muffle furnace at specified 600oC Temp. Where it inserted and then weighted again.

$$\%Total\ ash = (Ash\ wt / Wt\ of\ Sample) \times 100$$

Sadashivam practical book of Biochemistry [] Moisture Content was determined by hot air oven method. by Drying 2gm of groundnut seed at 103oC for 17 hrs in hot air oven. The percentage of moisture content was calculated on the wet weight (w/w) basis.

Biochemical Study

The estimation of minerals carried out by different method by practical book [2] of biochemistry by sadashivam by the different method and tests

Calcium – by volumetric method (pink colour)

Calcium precipitate as calcium oxalate and is treated with standard potassium permanganate which also act as self indicator.

Phosphorus – by spectrophotometric method (bluish colour)

For the determination of total phosphorus the sample in which organic matter has been destroyed by tri acid mixture, is used. The phosphate containing solution is treated with sulphomolybdic acid to produce phosphWorus molybdic acid. This is then reduced by stannous chloride giving a blue coloured complex whose colour intensity is proportional to the amount of phosphate in the preparation Iron – by colorimetric method (pink colour) Iron is determine the in food stuff after either dry or wet ashing of the food sample. A suitable aliquot of the mineral extract containing 0.1-0.5 microgram of iron is made to react with alpha alpha dipyridyl ind the presence of hydroxylamine hydrochloride to give a pink colour with absorbance maxima at 520 nm.

Germination Study

Three replication of seeds from each treatment were kept for germination at 25+2 degree temp and 90% relative humidity for 10 day using between paper method (BP) in germination chamber. The germination percentage was expressed on the basis of normal seedling only as described in ISTA rule(Anonymous 1999).

$$Germination\ \% = \frac{No\ of\ Normal\ Seeding\ Germinated}{Total\ No\ of\ Seed\ Place\ for\ germination} \times 100$$

RESULTS

Table 2. Effect of microwave Radiation on groundnut treated as well as control seed minerals by therotically

Treatment	Minerals		
	Calcium (µg)	Iron (µg)	Phosphorous (µg)
P ₁ T ₁	0.040	1.5	0.0045
P ₁ T ₂	0.360	1.5	0.0048
P ₁ T ₃	0.200	1.5	0.0036
P ₂ T ₁	0.240	1.5	0.045
P ₂ T ₂	0.12	1.0	0.036
P ₂ T ₃	0.240	1.5	0.005
P ₃ T ₁	0.160	1.5	0.0030
P ₃ T ₂	0.120	2.0	0.0026
P ₃ T ₃	0.080	1.5	0.005
Untreated Control	0.080	1.5	0.0058

The above value of minerals were practically done in laboratory from above value we can see normal change in minerals value with respect to treatment combination.

Fig.1. Graphical representation of minerals content calcium, iron, phosphorus treated as well as control seed of groundnut

RESULTS

Germination: With reference to several filter trails the parameter for voltage applied and duration of time of exposure were selected based on statistical requirement the experimental was planned for factorial randomized block design. There were nine treatment combination with three replication and one control all sample were kept in germinator on 8th Day. Germination count was made and fresh weight and root shoot length were measured. After that as ISTA international seed testing association recommendation the sample put in oven for 17hr at 60°C for measurement of dry matter content then weight at all sample were noted using these results. Germination study were calculated.

Table 3. Effect of microwave radiation on germination and root shoot length(cm)

Sr. No	Sample	Average Germination	Root Shoot Length (cm)
I.	P ₁ T ₁	44.5	20.05
II.	P ₁ T ₂	33.5	16.5
III.	P ₁ T ₃	38.5	17.7
IV.	P ₂ T ₁	45.0	17.4
V.	P ₂ T ₂	37.5	17.4
VI.	P ₂ T ₃	58.0	16.9
VII.	P ₃ T ₁	56.5	21.3
VIII.	P ₃ T ₂	43.5	15.7
IX.	P ₃ T ₃	31.5	14.2
X.	Untreated Control	39.5	15.2

From the observation table there is large different in germination average and root shoot length due to microwave radiation effect. Easily showed the observation table there is rate of average germination is greater than control.

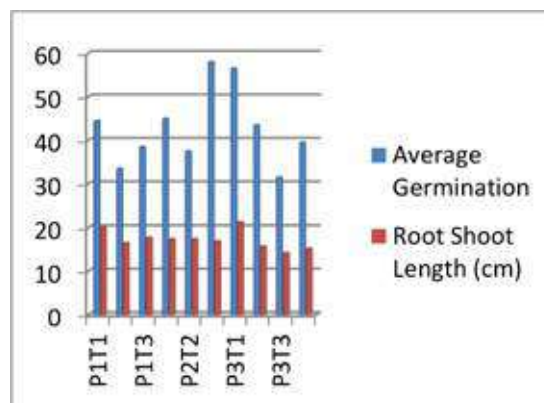

Fig 2. Graphical representation of Germination and Root Shoot length in cm Vs treated seed and control

DISCUSSION

The effect of microwave power level and exposure timing on germination on groundnut studied and data present in Graph no.1 present investigation the seed quality parameter decline progressively with increasing storage period it has been believe that biological process including free radicals, excite the activity of protein and enzymes which emergence, growth rate and seed vigour, which might have resulted better germination of onion seed during storage that untreated control. Shivare et at. (1971) reported the high seed germination could be maintained by using microwave power levels 0.25 w.g for seed of corn. However, Moon and chung (2000) recorded that the inhibitory effect of germination when electric field intensities exceeded 12 kv/cm for exposure time greater than 60 sec/in tomato. In Pea cultivator it has been found that the magnetic field presowing seed treatment can be used practically to enhance the growth and yield[7]

Root Shoot length

The effect of microwave power level and exposure timing root shoot length present in graph no. 1 electric field exposure of seed may result in breaking of hydrogen bounding in ultra structural elements of cell. This structural alternation may increase enzymes activity depending on the strength of electric field and exposure timing. This might have resulted increase in seed germination , seedling length and dry matter content which also increase the seed vigour than untreated control.

The seed recorded higher root shoot length dry matter content as compare with control the seed were treated with microwave power level 60% (P3) recorded root shoot length. Dry matter contain the seed which is untreated at exposure timing 10 sec(T1) recorded higher root shoot length than (T2) 20sec. T3(30 sec.).

CONCLUSIONS

- i. Exposure to action of high intensity AC electric field can be effective tool for the enhancement of germination and maintain the nutritional value.
- ii. The seed recorded significantly higher germination as compared to control. The seeds were treated with 80% microwave power level (p2) recorded higher germination percentage than 60(P3) and (100%) the seed were treated with exposure timing of 30 sec. (T3) and also give better germination result in 60% (p3) and time exposure to 10 sec.
- iii. The seed recorded higher root shoot length dry matter content as compare with control the seed were treated with microwave power level 60% (P3) recorded higher root shoot length . Dry matter contain the seed which is treated at exposure timing 10 se (T1) recorded higher root shoot length than (T2) 20 sec, (T3) 30 sec.
- iv. The seed recorded higher mineral contain as compared to control the seed which were treated with microwave power 60% P3 recorded higher mineral content than the seed which is treated and uncontrolled .There is no change in Phosphorous content. Iron content 100% time exposure to 20 sec. Gives better result.

ACKNOWLEDGMENT

The Authors are pleased to acknowledge Agricultural Engineering Department of Mahatma Phule Krishi Vidyapeeth, Rahuri and Chemistry department of New Arts Commerce and Science College Ahmednagar, for providing research facilities. Authors thank Prof. S. P Salave and D.S. Thanage for their help and support.

ABSTRACT

This study compares the performance of 3 old generation algorithms namely Genetic Algorithm, Particle Swarm Optimization and Differential Evolution with two new generation algorithms namely Firefly Algorithm and Symbiotic Organism Search in optimization of heat exchanger. The optimization procedure involves the selection of the major geometric parameters such as tube diameters, tube length, baffle spacing, number of tube passes, tube layout, head type, baffle cut, etc., as per TEMA standard and minimization of total annual cost is considered as the design target. The methodology takes into account the geometric and operational constraints typically recommended by design codes. Three different case studies are presented to demonstrate the comparative effectiveness and accuracy of proposed five algorithms. From the results of all the three case studies, it is concluded that DE performed the best in terms of capturing the lowest value of total cost and minimum execution time. The new generation algorithm, SOS performed the second-best as it captures the lowest values of total cost every time, honours the constraints every time in reasonably low execution time. The final optimized heat exchanger comply TEMA standard, having lowest cost and obey all geometry, velocity and service constraints.

Keywords : Heat Transfer; Mathematical Modelling; Heat Exchanger Design; Firefly Algorithm (FA); Symbiotic Organism Search (SOS); Differential Evolution (DE); Constrained Optimization.

INTRODUCTION

Heat exchanger (HE) remains as the most widely used heat transfer equipment in chemical process industries. Major chemical industries around the globe are facing unprecedented challenges due to shrinking profit margin and cut-throat global competition. Chemical industries are now looking for new ways to reduce their capital and operating expenditure (CAPEX and OPEX). Due to large numbers of HEs available in industries, a slight reduction of cost in heat exchanger (both CAPEX and OPEX) has multiplication effect. Hence, improvements in HE design methodology has attracted many researchers over the decades to minimize cost. HE design remains as potential area which can have a huge impact on the plant's profitability.

The traditional design of STHE involves heat transfer area and tube and shell side pressure drop calculations. Traditional design approaches does not take into account the cost of HE as main design target. It involves trial and error approach and does not guarantee the lowest cost HE. Detail design of HE involves thermodynamics, heat transfer and fluid dynamics calculations, strength calculations and last but not the least cost estimation. Various commercial software packages like HTRI, HTFS, ASPEN automates the thermal design and rating of STHE. In this software, designer needs to specify a priori various design decision variables like tube diameter, tube length, tube pitch, shell type, baffle spacing, baffle cut etc. from the standard values given in drop-down menu. Based on the user inputs, these software calculate various constraints like pressure drop, velocity through tubes etc. and check for any violation based on some industry-specific criteria. If any constraint gets violated, based on his experience, designer assumes new values of above geometric variables to explore the possibility of reducing the heat transfer area while obeying all the constraints. This type of trial and error approach is time-consuming and does not guarantee minimum cost design as cost minimization is not considered as design target.

Many gradient-based optimization techniques are tried in past by several researchers to minimize total cost. Researchers applying the gradient descent based traditional cost minimization techniques to STHE problem did not get encouraging results as most of the time, solution gets trapped in local optima. Hence, traditional optimization techniques are not proven to be very efficient and also, they have limited applications in complex heat exchanger optimization.

The second objective of the present study is to integrate the optimization algorithm of STHE with TEMA (Tubular Exchanger

Manufacturers' Association) standard. TEMA standards are followed by industry all over world to design and fabricate heat exchanger. From the literature survey, it was found that TEMA standard is not considered in the majority of published papers during the optimization of STHE. Hence, the resultant optimum STHE found in the literature does not comply with TEMA standard sizes and thus makes the fabrication cost higher. This makes the lowest cost heat exchanger with standard dimensions and easy for fabrication.

The third objective of the paper is to incorporate the best practices followed by different industries in HE design. In the actual shop floor of the industry, the lowest cost HE may not be always the best exchanger. Maintainability, less fouling tendency, less flow-induced vibration, ease of cleaning of tubes and shell, less floor space requirement, compactness of design are some of the criteria which must be considered during design of STHE. In the present study, we have incorporated those geometric and hydraulic constraints during the design optimization phase and thus ensure all these constraints are obeyed.

The optimal HE design problem

The calculation sequence of the optimum HE design has the following steps:

- 1) Assume a set of seven design variables like tube diameter, tube length, Ratio of baffle spacing to shell diameter, Number of tube pass, Type of pitch, Head type, Baffle cut %. These are the free optimization variables which need to be optimized to attain a lowest cost exchanger.
- 2) Estimate the heat transfer area based on required duty and assuming the values of design variables in Step 1.
- 3) Evaluate the shell and tube side pressure drop.
- 4) Based on the heat transfer area and pressure drop, calculate the capital cost, operating cost, and total cost.
- 5) Evaluate different constraints like velocity constraint, pressure drop constraint, geometric constraint, hydraulic constraint, and see whether all constraints are obeyed.
- 6) Iterate and select new set of values for design variables within their upper and lower bounds to minimize the cost.

Continue iteration until total cost is minimized and all the constraints are obeyed.

An attempt has been made in this work to apply different optimization techniques such as GA, PSO, DE, FA and SOS to design the lowest cost heat exchanger with TEMA dimensions (Table 1) and satisfying all of the constraints.

Table 1: Design variables and their options

Optimization variable	Variable Notation	Optimization variable	Options Available
x_1	d_o	Tube diameter	[0.00635, 0.009525, 0.0127, 0.01905, 0.022225, 0.0254, 0.03175, 0.0381, 0.04445, 0.0508, 0.05715, 0.0635]
x_2	L	Tube length	[1.2192 1.8288 2.4384 3.048 3.6576 4.8768 6.096 6.7056 7.3152]
x_3	R_b	Ratio of baffle spacing to shell diameter	[0.2 ,0.25, 0.3, 0.35, 0.4, 0.45, 0.5 ,0.55, 0.6 ,0.65, 0.7, 0.75, 0.8, 0.85, 0.9, 0.95, 1]
x_4	N_{Tubes}	Number of tube pass	[1, 2, 4, 6, 8]
x_5	P_t	Type of pitch	Triangular or Square
x_6	Head type	Head type	Fixed tube sheet or U tube, outside packed head, split ring floating head, and pull through floating head
x_7	Baffle Cut	Baffle cut, %	[15, 25, 35, 45]

Objective Function

The capital investment (C_i) can be obtained from Hall's correlation, which involves the C_i as the function of the HE surface area. The expression is as follows [21]:

$$C_i = a_1 + a_2 S^{a_3}$$

If the material of construction of the HE is stainless steel, the values of a_1 , a_2 and a_3 are 8000, 259.2, and 0.93, respectively.

The total discounted operating cost (Cod) can be computed by the following expression:

$$C_{od} = \sum_{x=1}^{ny} \frac{C_o}{(1+i)^x}$$

C_o is the annual operating cost formulated as below:

$$C_o = PC_e H$$

Where C_e is the energy cost and P is the pumping cost which can be expressed as below:

$$P = \frac{1}{\eta} \left(\frac{m_t}{\rho_t} \Delta P_t + \frac{m_s}{\rho_s} \Delta P_s \right)$$

The total cost (C_{tot}) is the summation of C_i and C_{od} and thus formulated as follows:

$$C_{tot} = C_i + C_{od}$$

Constraints

Table 2: Geometric, velocity and service constraints

Constraints description	Remarks
Geometric Constraints	
$3 \leq L/D_s \leq 5$	-
$0.2 \leq R_b \leq 1$	-
Velocity Constraints	
$v_t^{min} \leq v_t \leq v_t^{max}$ $1 \leq v_t \leq 2$ (in this case study)	Process fluids: 1 to 2 m/s, maximum of 4 m/s if it is required to reduce fouling; water: 1.5 to 2.5 m/s
$v_s^{min} \leq v_s \leq v_s^{max}$ $0.3 \leq v_s \leq 1$ (in this case study)	shell-side: 0.3 to 1 m/s
Service Constraints	
$\Delta P_t \leq \Delta P_t^{max}$ $\Delta P_t \leq 35000 Pa$ (in this case study)	For fluids having viscosity less than 1 mNs/m ² maximum pressure drop is 35 kN/m ² and for fluids having viscosity 1 to 10 mNs/m ² maximum pressure drop is 50-70 kN/m ²
$\Delta P_s \leq \Delta P_s^{max}$ $\Delta P_s \leq 35000 Pa$ (in this case study)	Shell side also has the same conditions as the tube side.

Optimization Algorithms

Symbiotic organisms search (SOS), Firefly algorithm and Differential evolution is given to understand their working principle. GA and PSO algorithm are also used in the present study but their working principle are not given here for the sake of brevity. More details of all the algorithms can be found in reference Yang [10].

Symbiotic Organisms Search (SOS):SOS is a nature-inspired metaheuristic optimization technique proposed by Cheng and Prayogo [11]. This method basically imitates the relationship among different organisms.

Firefly optimization (FA):Firefly optimization algorithm (FA), proposed by Yang [13] mimics the periodic flashing behaviour of fireflies.

Differential Evolution (DE): DE is one of the old metaheuristic optimization methods and has been proved to be very effective in solving many real-life optimization problems.

Testing of algorithms against heat exchanger optimizations through a case study:

The data as shown in **Table 3** were supplied as input to the different optimization algorithm. This case study is taken from Kern [6]. Each optimization algorithm was run 100 times due to the stochastic nature of such algorithm and the best out of 100 runs was taken as the final optimum value for that algorithm. One distinctive feature of the present study, which differs from the earlier research work, is that in the present study, the optimization algorithm is forced to take discrete standard values as per TEMA standard. It cannot take any other values, which are not standard. This ensures that the final design obtained after optimization complies with TEMA standard. For other optimization variables also discrete values as per TEMA standards are taken, and those values are given in **Table 1**. All the values of discounted operating cost are computed with $n_y = 10$ years, annual discounted rate $i = 10\%$, energy cost (C_e) = 0.12 €/kW h. Annual amount of work hours (H) = 7000 h/year.

Table 3: Process parameters and physical properties of the case study

Condition	Mass flow (kg/s)	T_{input} (°C)	T_{output} (°C)	ρ (kg/m ³)	C_p (kJ/kg K)	μ (Pa.s)	K (W/m K)	$R_{fouling}$ (m ² K/W)
Shell side: methanol	27.8	95	40	750	2.84	0.0034	0.19	0.0003
Tube side: sea water	68.9	25	40	995	4.20	0.0008	0.59	0.0002

Table 4 shows the optimum HE results of 5 metaheuristic algorithms, namely GA, PSO, DE, SOS, and FA, along with their original design solutions given by the referenced authors.

Based on the performance to capture the minimum value and execution time, the following sequence can be made:

- 1) DE (Capture the lowest value and the lowest execution time)
- 2) SOS (Capture the lowest value and the second-best execution time)
- 3) PSO (Capture the lowest value, execution time is very high)
- 4) FA (Did not capture the lowest value, however reasonably low execution time)
- 5) GA (Did not capture the lowest value and reasonably low execution time)

We also observed that the total cost has increased from 37064.04 € to 38687.15 € when the constraints are imposed. Therefore, the difference of 1623.11 € is due to the imposing constraints mentioned in Table 2 but it ensures the best performing HE.

Table 4: Results of optimization

*Did not obey the constraints

Observations

The optimization algorithms are able to reduce the total cost from 64480 € (literature) to 37064€ i.e., 43 % decrease in total cost when no constraints were imposed. However, when constraints were imposed, minimum total cost was achieved 38687 € i.e., equivalent to 40% reduction in total cost. In other words, the cost of imposing constraints is around 1623 €.

From the results, we can conclude that DE performed the best among all algorithms in terms of capturing the lowest value of total cost and minimum execution time. The new generation algorithm, SOS performed the second-best as it captures the lowest values of total cost every time, honours the constraints every time in reasonably low execution time. PSO captures the lowest values every time, but its execution time is excessively high as compared to DE and SOS. FA has reasonably well execution time, but it fails to attend the lowest values of total cost in all three cases. Therefore, as observed from the results of three case studies, SOS is the most promising new generation algorithm, and DE being old generation classical algorithm, still performs the best among all the five algorithms.

The major advantages of these type of case studies are as follows:

- It helps the designer to locate the minimum cost HE very quickly without trial and error.
- Use of different algorithms enables the designer to validate the final optimum results as the most of the algorithms converge to same minimum value. Agreement of final results by five different algorithms increase the confidence of designer about his calculations
- The imposition of different constraints in optimization algorithms enables the HE maintainable, robust, and compact.

Use of discrete decision variables ensures that the final optimized HE would comply with TEMA standard, which is followed by the industry globally.

Fig 1: Comparisons of total cost, capital cost and operating cost obtained from different algorithms for case study

CONCLUSIONS

This study applies 5 metaheuristic algorithms on heat exchanger optimization problems and able to find out the lowest cost heat exchanger automatically. From the comparative study results, it is concluded that SOS has great potential among new generation algorithms. However, DE performs best in heat exchanger optimization problem. Instead of picking up any random value between lower and higher bound, this study enforced picking up only TEMA specified discrete values for tube diameter, tube length etc and thus ensure that the resultant heat exchanger coming out from algorithms comply with TEMA standard. Also, various best practices in heat exchanger design followed by industry is incorporated in the design algorithm in terms of geometry and hydraulic constraints so that optimum heat exchanger performs best in the shop floor in spite of its lowest cost.

ABSTRACT

India has committed to have 40 per cent of its electricity capacity from non-fossil fuel sources. Biogas is one among the major source of renewable energy. In this research an attempt is made to provide heat to the bio mass in the digester in a passive manner so that no energy is spent in generating and transferring heat. Solar energy is harvested and transported to the digester through helical coil and the performance of bio-digester is studied. Initially the digester was started without heat source and experiments are conducted with cow dung followed by food waste and solid waste. The same experiment is repeated with heat source. It can be analyzed clearly that addition of heat source enhances the generation of bio gas.

Keywords : Bio mass, Helical coils, Solar water heater.

INTRODUCTION

Biomass is organic material that comes from plants and animals, and it is a renewable source of energy. India is very rich in biomass and has a potential of 16,881MW (agro-residues and plantations), 5000MW (bagasse cogeneration) and 2700MW (energy from waste). Biomass power generation earns investments of over Rs.600 crores every year, generating more than 10 million man-days in the rural areas. It briefly explains about anaerobic digestion process, steps involved and the parameters affecting the digestion process[1]. Methanogenesis is a critical step in the entire anaerobic digestion process, as it is the slowest biochemical reaction of the process[2,3]. It is severely influenced by operation conditions. Composition of feedstock, feeding rate, temperature, and PH are examples of factors in methanogenic process. Carbon and nitrogen concentration are essential constituents for the optimal growth of bacteria in anaerobic digester[4,5]. Universally adopted carbon nitrogen range is 25:1 to 30:1. Deviation from this ratio will slow down the process. Thus biomass has a greater advantage in the production of energy as they are easily available[6], economically cheap and environmentally friendly[7]. There are various technique and methods for the biomass conversion[8]. This project uses biogas digester to produce methane which is the main portion of biogas which can be converted to other form of energy such as heat and electricity. The outcome of the research is to analyse the digester performance using the passive heat source.

METHODOLOGY

The design of anaerobic digester with solar water heater and develop a heat exchanger coil. A technique is developed for measuring the quantity and quality of biogas and various experimental results are obtained with and without heat source.

Design of the anaerobic digester with solar water heater

Anaerobic digester plant is used to produce the digestion process where the organic matter is converted in to useful gases. The design and technology of biogas plant differs from country to country, depending on climatic conditions and national frameworks, energy availability and affordability. Many types of digesters were designed and the few categories are listed, 1.fixed dome 2.floating drum 3.bag digesters 4.plug flow digester 5.anaerobic baffled reactors.

Among these, nano gas digester is selected because the volume of gas produced can be found in this digester and size of plant. Dimensions of the digester is,

Height of digester (h1) = 65 cm

Height of gas dome(h2) = 28.5cm

Dia of digester (d_1) = 46 cm

Diameter of dome (d_2) = 44 cm

Volume of digester and gas holder is 105 litres and 45 litres.

Fig 1. Bio Gas Digester

Selection Of Heat Source

Heat energy is given to the biomass in the digester to increase the temperature of the slurry. Solar energy is used as heat source where it is abundant in nature, it is the renewable source of energy. These radiations are converted to other forms of energy such as heat and electricity. Some types and apparatus are used to do this conversion and main conversion types are solar electric energy and solar thermal energy. Here, in order to improve the performance of a collector it is necessary to reduce the heat loss by convection on the top side of the collector as in Fig. 1. This is done by having vacuum above the absorber plate i.e., evacuated tube collector using thermosyphon effect. As a consequence, it becomes to use a glass tube as the cover because only a tubular surface is able to withstand the stresses introduced by the pressure difference. The dimensions of the solar collectors are,

Inner tube diameter (d_1) = 35mm

Outer tube diameter (d_2) =45mm

Tube length (L) =600mm

Diameter of the tank =130mm

Length of the tank =600mm

Volume of tank =30liters

Design and Fabrication of Heat Exchanger Coil

Heat exchanger is a device used to transfer heat energy from one fluid to another generally from hot fluid to cold fluid. They are used in many applications for both heating and cooling. In our project these coils are used to heat the slurry in the digester.

The software used for designing the heat exchanger coil is “BS Solid works 2015”. In that various coils were designed such as helical coil, spiral coil, spherical coil and S-shape coil. Among these helical coil with the tapering side is selected because it fits inside the digester exactly and large amount heat transferring area is achieved in this design as shown in Fig. 2.

The specifications of the coil is,

Diameter of the coil =1.2cm

Length of coil =750cm

Height of the coil =21cm

Number of turns =11turns

Fig 2. S-Shape Coil And Spiral Coil

Material used for the coil is copper because of its good heat transfer properties. Copper has the thermal conductivity of 386W/mK which is a good conductor.

EXPERIMENTATION

The biogas digester, solar water heater which acts as heat source and the heat exchanger coil is brought into a single setup. Heat exchanger coil is placed inside the digester and it is made leak proof so that hot fluid does not mix with the slurry in the digester at any situation. At first the digester is drilled and two holes were made for outlet and inlet entry of fluid. The heated water from the tank enters the top of the coil and the heat transfer takes place from the oil to the slurry as the water moves downwards the temperature is reduced and reaches the outlet and enters into tank, the process is repeated. As the slurry gets heated, the decomposition and microbial generation becomes faster and bio gas is produced quickly. They are collected in the gas holder and the quantity is measured with the help of scale in gas holder. To test the quality of the bio gas Zakaria tube is used. The quality of biogas depends upon the presence of methane in it. Zakaria tube is a U-tube structure made up of glass with markings up to 5ml and internal dia 12mm. Saturated solution of potassium hydroxide solution (KOH) is prepared by dissolving pellets and poured into a tube. This solution is capable of absorbing all carbon di oxide in biogas. The biogas produced from digester is collected in 5ml syringe and injected into a tube .the value of methane and carbon dioxide is noted in a table which is used for analysing the quality of biogas.

RESULT AND DISCUSSION

The experiments were conducted with and without heat source and the results are displayed in graphical form for the easy understanding and comparison that includes the specific biogas yield, specific methane yield, retention time and quality of biogas. Specific biogas yield is the ratio of total volume of gas produced to the total mass of feed stock added for digestion. As biomass is feed in to the digester, the digester starts to digest the food waste and produce the biogas. The gas produced form the biomass which we use cow dung, food waste and municipal solid wasted are listed below.

Methane gas produced from the biomass is the result of methation process and the percentage of methane produced is measured using zakaria tube. The total amount of gas produced for 15 days these values are added up and it is the total volume of gas produced. The total mass of biomass for every process is 50kg. total volume of gas produced is divided by mass and it is the Specific Gas yield. In terms of methane volume of divided by the mass. The values are tabulated and graphs are drawn.

Quality of biogas

From the below table and figure that blue bar indicates the quality of the biogas when there is no heat supplied and it is found 70% for cow dung, 62% for food waste and 55% for MSW and they are in good quality as in **Table 1**.

Table 1. Relationship between Net Calorific Value and Percentage of Methane

S.no	Methane content (%)	Net Calorific Value (Mj/m ³)
1	50	20
2	65	22
3	70	25

The biogas produced from the feedstock is in good quality for combustion, among that the biogas produced from the cow dung

has high quality with methane percentage of nearby 70% and it has the calorific value nearby 25 Mega joules per meter cube. The percentage of methane in the biogas before and after the applying of heat source heat source is tabulated in **Table 2**, the values marked here is the percentage of methane in the stable region of biogas yield.

Table 2. Percentage of Methane (%) for 15 Days

S.NO	Biomass	Percentage of Methane (%)	
		Without heat	With heat
1	Cow dung	70	64
2	Food waste	62	55
3	MSW	55	52

UNCERTAINTY ANALYSIS

- In the open test there are some variation in the results and the percentage of uncertainty is about 10%.
- From Zakaria tube the uncertainty in the results about 5%.
- Due to fouling and scaling of the heat transfer coil the uncertainty is about 3%.
- The temperature indicator has its uncertainty about 3%.
- The total uncertainty of the project is about 21%.

Table 3. Quality of bio gas

The red bar indicates methane quality with heat source and it is 64% for cow dung there is reduction of 6% percentage, food waste shows 55% and it also has some reduction 8% and for MSW it is 52% and it reduces from 55% though the quality reduces they are in combustible zone where biogas 50% of methane is combustible.

Specific Biogas Yield 15 Days

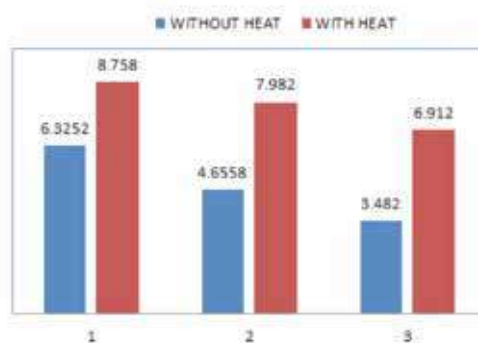

Fig 3. Specific Biogas Yield for 15 Days

The Fig. 3 is drawn for Specific biogas yield for the period of 15 days. In this chart blue bar indicates the specific biogas yield without heat source and the red bar indicates the specific biogas yield with the heat source. The cumulative biogas yield from Cow dung, Food waste and MSW without heat source is 316 liters, 232 liters and 174 liters respectively. The specific gas yield is 6.3 liters for Cow dung, 4.6 liters for Food waste and 3.4 liters for MSW. The red bar indicates the biogas yield with heat source and the cumulative gas produced by applying heat is 437 liters, 399 liters and 345 liters for Cow dung, Food waste and MSW. The specific gas yield is 8.7 liters for Cow dung, 7.9 liters for Food waste and 6.9 liters for MSW. It is clearly seen that the when heat is supplied the specific gas yield increases from 6.3 liters to 8.7 liters for Cow dung. Food waste shows a variation in biogas yield from 4.6 liters to 7.9 liters and MSW shows a good production in biogas from 3.4 liters to 6.9 liters that is it is almost doubled.

Specific Methane Yield 15 Days

Fig 4. Specific Methane Yield for 15 Days

The Fig. 4 is drawn for Specific methane yield for the period of 15 days. In this chart blue bar indicates the specific methane yield without heat source and the red bar indicates the specific methane yield with the heat source. The cumulative methane yield from Cow dung, Food waste and MSW without heat source is 185 liters, 116 liters and 78 liters respectively. The specific methane yield is 3.7 liters for Cow dung, 2.3 liters for Food waste and 1.5 liters for MSW.

The red bar indicates the methane yield with heat source and the cumulative methane produced by applying heat is 223 liters, 116 liters and 78 liters for Cow dung, Food waste and MSW. The specific gas yield is 4.4 liters for Cow dung, 3.4 liters for Food waste and 3.2 liters for MSW. It is clearly seen that the when heat is supplied the specific gas yield increases from 3.7 liters to 4.4 liters for Cow dung. Food waste shows a variation in methane yield from 2.3 liters to 3.4 liters and MSW shows a good production in methane from 1.5 liters to 3.2 liters that is it is almost doubled.

CONCLUSIONS

In this project a hybrid digester with solar water heater has been designed, fabricated and experiments were successfully carried out. The result show the performance of digester has increased by applying heat energy. A passive mode of heat transfer is achieved by thermo syphon effect, thus the cost of the system is reduced. The fabricated model is a successful one and it can be converted into large scale. Additives and be developed for digesting solid waste.

A New Generic Methodology for Modelling and Optimization of Running Commercial Chemical Plant to Balance Profit and Negative Environment Impact with Cumene Production Plant as Case Study

Somnath Chowdhury, Sandip Kumar Lahiri*

Department of Chemical Engineering, National Institute of Technology Durgapur, West Bengal

✉ sandipkumar.lahiri@che.nitdgp.ac.in*

ABSTRACT

The research work mainly emphasizes on the establishment of a methodology that will help to delicately balance the negative environmental impact created by the industries and profitability of the plants. A case study of cumene manufacturing plant is considered. At first, Aspen simulation of the cumene plant was performed. After that, the sensitivity analysis of the key parameters was carried out to generate data which was used for the development of artificial neural network (ANN) model. This model was used to generate Pareto optimal solutions of three pairs of variables viz. vent flow & product flow, reboiler heat duty & product flow, reboiler heat duty & vent flow. Besides these, another Pareto optimal solution of Profitability vs. Eco-indicator 99 was also generated. Eco-indicator 99 reflects the negative environmental impact of a product starting from its production to its consumption. To obtain these Pareto solutions, multi-objective firefly optimization (MOF) was applied. The developed methodology is generic and can be applied to any running process plant on real-time basis.

Keywords : Modelling; Optimization; Aspen Plus; ANN; Multi-objective Firefly; Eco-indicator 99.

INTRODUCTION

Due to rapid industrialization in last three decades and the negative impact on environment created by oil, gas, chemical, mineral processing, and metal industries, the time has come to relook the way these industries are running. Cutthroat global competition forces these industries to run the plant at maximum capacity ignoring the negative environmental impact and higher energy consumption. Due to the devastating negative impact on health and environment in the last decade, these companies are now looking for sustainable solutions which will fulfill the following three objectives: (i) maximize production and profit, (ii) minimize environmental impact, and (iii) maximize energy efficiency. As these three objectives are contradictory with each other, there is a need to develop a methodology which will optimize the running plants by properly balancing these three contradictory objectives. In this work, a methodology involving Artificial Intelligence (AI) based modelling, and metaheuristics-based optimization technique has been developed which will evaluate the optimum operating conditions of running plant so that all the three contradictory objectives are simultaneously optimized.

In this work, cumene plant was considered as a case study to demonstrate step-by-step methodology of modelling and optimization of running plants. Cumene is produced by the reaction between benzene and propylene. Fig. 1 illustrates a simplified schematic of cumene plant, where benzene and propylene are fed into a reactor and cumene is produced. The outlet of the reactor is fed to a Flash Drum (FD) to remove the inert propane, which comes as an impurity in propylene feed. Top of the FD consist of propane and unreacted benzene is either vented off or burnt as fuel and have a significant negative environmental impact. The bottom of the FD essentially consists of unreacted benzene, cumene, heavier compounds are fed to a distillation column, Benzene Recovery Column (BRC) where benzene is separated as top product and is recycled back to reactor. The bottom product consists of cumene, and heavier compounds is fed to another distillation column namely Cumene Recovery Column (CRC), from where pure cumene (99.5% w/w) is separated as top product. The bottom product consists of heavier compounds is considered as low-value product or waste. The main objectives of this study is to develop an optimization framework which can be used in real-time in plant environment to find out the optimal reactor condition (temperature, pressure, benzene, and propylene flow ratio), FD temperature, and pressure so that the following objectives are met: (i) Maximization of cumene product flow (to maximize profit), (ii) Minimization of the vent from the FD (to minimize environmental impact) and

(iii) Minimization of summation of heat duty of reboilers of two distillation columns (to maximize energy efficiency). Since the reaction is exothermic, the maximum reactor heat removal capacity was put as a constraint.

This methodology utilized the first principle-based Aspen simulation to develop the base case simulation model of the whole cumene plant. A large number of operating data is generated from the Aspen model with a sensitivity analysis. These simulation results were used to develop an Artificial Neural Network (ANN) based model so that it can be utilized in real-time basis in the plant. Once an accurate ANN model is developed, operating conditions were optimized by recent Multi-Objective Firefly (MOF) algorithm, which generated Pareto diagram that can be used by the plant personnel to get the best suited optimum result as per their priority [1]. The scientific novelty of this work is as follows: (i) This developed methodology is generic and can be applied to any process plant which has a significant environmental impact, (ii) It contains first principle-based and data-driven AI-based modelling technique for the development of a correlation which can be readily used to predict the plant output from its operating condition, (iii) It utilizes MOF algorithm to solve a real-life multi-objective problem and found delicate balance between profit and environment impact.

METHODOLOGY

Aspen-based modelling of commercial cumene plant

Aspen Plus is a powerful software package used for the design and simulation of a variety of processes [2]. Aspen Plus uses mainly first principle-based phenomenological modelling technique and that is why the models have the explainability of their own. In this study, Aspen Plus V8.8 was used for the simulation of cumene production plant, the schematics of which has been illustrated in Fig. 1. For the REACTOR, built-in reactor model namely RGIBBS was used. RGIBBS model is generally used where the reaction kinetics are unknown. RGIBBS actually solves the model by minimizing the Gibb’s free energy. The detail of process simulation input has been depicted in Table. At first, a base case simulation was executed. In the Flowsheet analysis of Aspen plus, there is a feature, namely Design Spec. If a particular output variable is set by iterative method, Aspen Plus changes the input variables in such a manner that the particular output reaches the target value. In this study, three Design Specs were applied to the base case simulation wherein the targets were fixed as follows:

- a) 99.9 % (w/w) purity of benzene at BRC top
- b) 99.5 % (w/w) purity of cumene product at CRC top
- c) 99.9% recovery of cumene as top product.

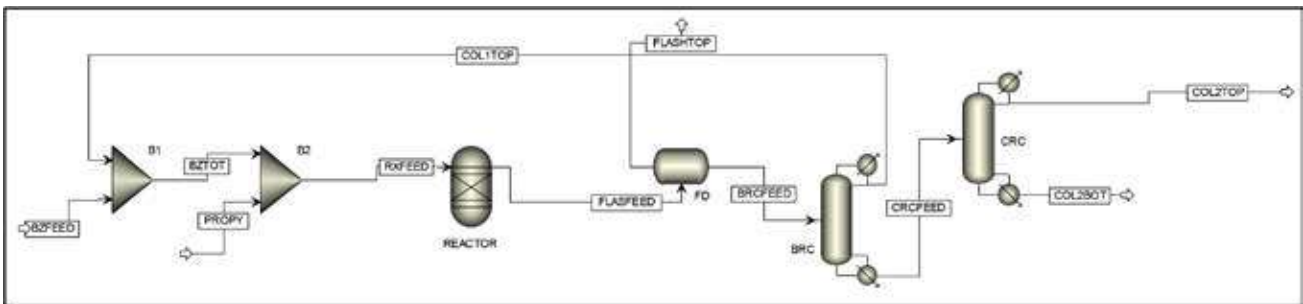

Fig. 1. Process flow diagram of cumene production

Sensitivity analysis of base case Aspen model

Sensitivity analysis is another model analysis tool of Aspen Plus. Using this tool, user can visualize the variation of target output variables by changing the manipulated variables in a given range of values. Operating parameters/ decision variables viz. Feed flow of benzene, propylene, reactor, FD temperature and FD pressure were varied with $\pm 25\%$ from their base case values. Cumene flow, FD vent flow and summation of heat duties of two reboilers were considered as outputs. The main aim of performing this sensitivity analysis is to form a large database of input and output variables so that using this database, the ANN model can be developed.

ANN Modelling

ANN, an effortless data-driven modelling technique has gained a vast popularity thanks to the advent of artificial intelligence

applications in diverse fields. The strength of ANN lies in its capability to handle noise in the data, performing efficiently with multiple output system, efficacy to learn non-linearity and complex relationship [3]. ANN uses multi-layer perception in its network architecture.

In this study, the database developed from sensitivity analysis was used for building up of ANN based model. ANN based modelling was developed because of the following reasons:

- (i) It is not possible to integrate and run the Aspen model in real-time due to its longer execution time.
- (ii) With the Aspen model, multi-objective optimization is difficult to execute.
- (iii) Aspen Plus in-built optimization process has a large possibility to be stuck in local optima, whereas since metaheuristic optimization technique undergo random search in the search space, its possibility to be stuck in local optima is comparatively less.

Here, to build-up the network architecture, 10 number of hidden neurons were used. Different activation functions were tried among which tan-sigmoid activation function gave the best predictability. For training the network, Levenberg-Marquardt back propagation technique was applied. To evaluate the performance of the ANN model, two statistical parameters, namely, coefficient of determination (R2), and Average Percentage Error (APE) were used.

Multi-objective firefly algorithm: at a glance

Multi-objective optimization problems are more complicated in comparison to single-objective optimization as unlike single-objective, a multi-objective optimization problem has no single unique solution, but it has multiple non-dominated solutions, and this set of solutions is called Pareto optimal solutions.

Firefly optimization algorithm is inspired by the flashing characteristics of the firefly. The following rules have been applied in this algorithm [1]:

- (i) Regardless the sex, one firefly attracts others by generating flashes
- (ii) The attractiveness is essentially measured by the brightness of the flashes. Obviously, the more the brighter is the flash, the other fireflies will be attracted more.
- (iii) So, in the search space of the optimization, the brightness of the firefly is determined.

The brightness of the flash of firefly $I(x)$ is proportional to the objective function $f(x)$ but the attractiveness β is relative and adjudged by the brightness of others. The β can be represented by the following equation (1):

$$\beta = \beta_0 + e^{-\gamma r^2} \tag{1}$$

Where r is the distance between two fireflies, β_0 denotes brightness at $r = 0$, and γ represents the absorption coefficient. The attractiveness varies in the range of $\beta_0 - \beta_0 e^{-1}$. If positions of two fireflies, namely i and j are represented by x_i and x_j respectively, then the distance between them is $r_{ij} = \|x_i - x_j\|$. Due to more attractiveness, the movement of i towards j can be expressed as follows (2):

$$x_i^{t+1} = x_i^t + \beta_0 e^{-\gamma r_{ij}^2} (x_j^t - x_i^t) + \alpha_t \epsilon_i^t \tag{2}$$

Where the second term and third term at right-hand side of (2) represents the attraction and randomization, respectively. In each iteration, the location of the fireflies is updated. With the principle stated above, multi-objective firefly (MOF) optimization was developed to find out the set of Pareto optimal solutions. The Pareto optimal is defined as: “ x^* is Pareto optimal if there exists no feasible vector of decision variables which would decrease some criterion without causing a simultaneous increase in at least one other criterion” [4].

To obtain $Pbest^t_*$ the $\psi(x)$ has to be minimum. The $\psi(x)$ is the weighted combination of the two objective functions, the expression of which is mentioned below (3):

$$\psi(x) = w_1 f_1(x) + w_2 f_2(x) \tag{3}$$

where w_1 and w_2 are the weights, the summation of which is equal to 1.

If a firefly is not dominated by others, then it takes a random walk, which can be expressed as below (4):

$$x_i^{t+1} = Pbest_i^t + \alpha_i \varepsilon_i^t \quad (4)$$

In this study, after the development of reliable model, it was subjected to optimization. MOF was applied as an optimization tool to generate optimum operating condition, which can balance the contradictory objectives, which are:

- (i) Maximization of product flow and minimization of FD top vent flow,
- (ii) Maximization of product flow and minimization of summation of heat duties of two reboiler,
- (iii) Maximization of FD top vent flow and minimization of summation of heat duties of two reboiler.

Here, maximum heat recovery from reactor was put as constraint.

Environment impact through Eco-indicator 99

In this research work, Eco-indicator 99 (Eco 99) has been used as a key indicator of the environmental impact. In a holistic approach, Eco-indicator 99 measures the total environment and health impact of the chemical production process, based on the methodology of the Life Cycle Analysis (LCA) [5]. Eco 99 includes all the negative impacts such as Carcinogens, Climate change, Ionizing radiation, Ozone depletion, Respiratory effects, Acidification, Ecotoxicity, Land occupation, Fossil fuels, Mineral extraction, etc. and quantify them with realistic numbers [5]. Every chemical product has a negative impact on the environment. The impact starts from raw material processing, followed by product manufacturing, distribution, and packaging. Furthermore, additional environmental impact occurs during the product's usage as the product consumes energy and material. If environmental damage caused by the product has to be measured, then the inclusion of its whole life cycle phases has to be carried out, and this analysis is called Life Cycle Analysis (LCA). For a designer, performing an LCA is a difficult and time consuming task. The Eco 99 has resolved this problem in the following manner:

- (i) Eco 99 uses the LCA method and comes out with a single numerical score, which represents the total environmental impact caused by the particular product.
- (ii) Data has been collected in advance for the most common material, and processes and the eco indicator scored has been assigned from this.

In holistic approach, minimization of Eco 99 automatically imitates the minimization of FD vent flow and heat duties of the reboilers. This is also a fact that Eco 99 minimization affects the profitability of the plant. Therefore, in this study MOF was again applied with two contradictory decision variables viz. Eco 99 and profit to obtain Pareto optimal solutions.

RESULTS AND DISCUSSION

A. Accuracy of ANN model The predictability of the ANN model was adjudged by determining R^2 and AEP. The values of R^2 was found to be 0.99, and the AEP was obtained as 0.5%. Looking at the R^2 values to be close to 1 and reasonably low values of AEP, it can be inferred that the ANN model is quite accurate and reliable to be used for optimization study.

Optimization

By applying MOF on the developed ANN model, the Pareto solutions were generated, which have been plotted in **Fig. 2** and **Fig. 3**. **Fig. 2a** clearly shows that if product flow is increased, then the heat duty of the reboilers has to be increased, which results in a rise in negative environmental impact. It is because the rising heat duty of reboilers means an increment in steam consumption. **Fig. 2b** indicates that if vent flow is kept at the lower side, the reboiler heat duty will be at the higher side as there will be more feed to the BRC and CRC. Increment in vent flow or in reboiler heat duty, in any case, more negative impact on the environment will be there. **Fig. 2c** depicts that if vent flow increases, there will be a decrease in product flow.

Fig. 3 illustrates the Pareto diagram of the Profit vs. Eco 99. From this plot, it can be seen that if profit is increased, negative impact on environmental will also increase, which is always the case for most of the chemical industries. Increasing the profit means running the plant with higher capacity and higher production of cumene. In **Fig. 3**, it can be visualized that profit is the highest at point C, but there the Eco-99 is also the highest, which essentially means that a very high profit can be achieved only by hampering the environment. At point A, both profit and Eco-99 are on the lower side. But if we go from A to B, profit has been increased drastically, but Eco-99 does not increase much. So, it is better to operate the plant in such a manner that the vent flow, heat duty of the reboilers and product flow remain at corresponding to the point B because in this condition, profit would be obtained is reasonably high, but the environmental impact will remain at a lower side.

SCIENTIFIC NOVELTY

This work developed an ANN-based model of cumene manufacturing unit using data developed by the sensitivity analysis employing Aspen Plus simulation of the same plant. The model can be utilized on a real-time basis in a running process plant. Operating conditions were optimized by recent MOF. The scientific novelty of the current work is as follows:

- (i) A generic methodology has been developed which addresses the core issue of chemical plants i.e., how to maintain a delicate balance between profitability and environmental impact. The developed methodology generic and can be applied to any process industries which have a significant environmental impact. The methodology is applicable in those running plants where designing modification is not possible.
- (ii) In this work, the concept of Eco- indicator 99 is introduced to take into account all the negative health and environmental impact a manufacturing process can produce during its operation. This holistic approach to accounting environmental impact can be a reliable methodology to optimize the process parameters of running the commercial chemical plant.
- (iii) It has utilized a recently developed MOF algorithm, which was able to solve real-life optimization problem and found a delicate balance between profit and environmental impact.

Fig. 2. Pareto diagrams of (a) heat duty of reboilers vs. product flow, (b) heat duty of reboilers vs. vent flow, (c) vent flow vs. product flow

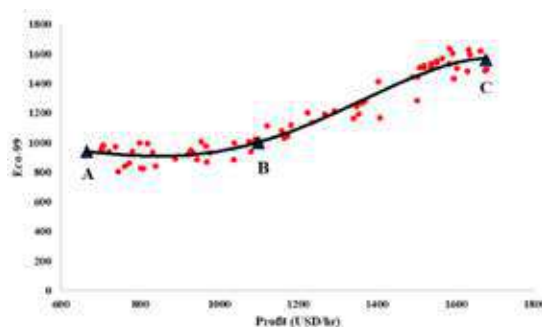

Fig. 3. Pareto diagram of profit vs. Eco-99

CONCLUSION

This work developed a new modelling and optimization methodology, which can be used by commercial chemical plants to quantify their environmental impact and find a delicate balance between profit and environmental impact. This work shows an easy way to use Aspen Plus and ANN modelling methodology for commercial plants. Multi-objective hybrid ANN and firefly algorithm has been used in the present study to find a delicate balance between profit and environmental impact. The effectiveness of the proposed methodology is shown through a case study of commercial cumene manufacturing process. The proposed methodology develops a Pareto optimal solutions platform to gain insights into the balance between profit and environmental impact. These insights may be very useful to the plant management to take informed decision regarding plant operations.

The developed methodology utilized the Aspen simulation, latest AI based modelling and nature-inspired optimization technique and is generic, which can be extended to any other running plant. The optimizer can be run on a real-time basis, and the optimal conditions can be evaluated in the ever-changing dynamic environment of the plant. The developed methodology balances between profit and environmental impact in totality for running a chemical plant.

ABSTRACT

The present work emphasizes the development of a generic methodology that addresses the core issue of any running chemical plant, i.e., how to maintain a delicate balance between profit and environmental impact. Here, commercial vinyl chloride monomer (VCM) production plant has been taken as a case study. This work developed a new modelling and optimization methodology, which can be used by commercial chemical plants to quantify their environmental impact and find a delicate balance between profit and environmental impact. This work shows an easy to use Aspen and ANN modelling methodology for commercial complex reactors. Multi-objective hybrid ANN and genetic algorithm has been used in the present study to find a delicate balance between profit and environmental impact. The effectiveness of the proposed methodology is shown through a case study of commercial VCM manufacturing process. The proposed methodology generates optimum operating conditions of VCM reactor, which can be implemented in commercial plants to boost profit. Moreover, the proposed methodology develops a Pareto optimal solutions platform to gain insights of the balance between profit and environmental impact. These insights may be very useful to the plant management to take informed decision regarding plant operations.

Keywords : Aspen simulation; Multiobjective Genetic Algorithm; ANN, sensitivity analysis; Pareto.

INTRODUCTION

For the last three decades, chemical industries have produced a lot of chemicals with the sole objective of profit maximization. On operating a plant with a philosophy of profit maximization, the chemical industries have damaged the environment drastically. Lately, the industries have realized that the industries cannot succeed in the long run by damaging the environment and hence there is a thrust to find a sustainable solution. The main hindrance chemical industries are facing today in their journey to reduce their negative environmental impact is that it hits their bottom line and reduce their profit margin. Last decade giant chemical industries across the globe have operated their plants with maximum capacity in order to maximize the profit and to survive in the global business competition. While running those plants at the highest capacities, these industries have also maximized the environmental damage. To reduce the environmental impact, these companies either have to reduce their capacities or have to install pollution control equipment, both of which hit the bottom line of the profitability.

Vinyl chloride monomer (VCM) is one of the world's most important and largest commodity chemicals. VCM is used primarily for the production of polyvinyl chloride (PVC) homo-polymer and copolymer resins. PVC has the advantage of being utilized in conversion and fabrication processes with great flexibility, such that end products cover a wide range, including pipe and fittings, profiles and tubes, siding, wire and cable, windows, doors, floorings, film and sheet, and bottles.

In this study, our objective was to find a sustainable solution for the VCM plant. Finding a sustainable solution is a multi-objective optimization problem where we increase the product (VCM) flowrate and simultaneously reduce the energy consumption and environmental damage by venting. This industrial case study has developed a modelling and optimization framework which can be deployed in a commercial plant for simultaneous achievement of three contradictory objectives, such as profit maximization, energy conservation and reduce environment damage.

Problem Description

In this study, we have considered the production of vinyl chloride monomer from ethylene dichloride, by following the reaction:

In the VCM plant flowchart, 1000 kmol/hr of pure EDC feed, at 20°C and 30 bar is entering a reactor, where the cracking reaction takes place at 500°C and 30 bar. The reactor outlet stream is let to a cooler with a 10 degrees sub-cooling with a 0.5 pressure drop. The stream from the cooler outlet is fed to the first distillation column with 15 stages. A reflux ratio of 1.082 and a distillate to feed ratio of 0.34 is maintained in this distillation column. The feed enters above stage 8 and a column pressure of 25 bar is maintained. The distillate of this column which is HCl is vented out, while the bottom stream is fed to another distillation column of 10 stages. A reflux ratio of 0.969 and a distillate to feed ratio of 0.55 is maintained in this column. The feed enters the second distillation column above stage 7 and a column pressure of 8 bar is maintained. The distillate is the product stream containing VCM while the bottom stream is recycled back via a pump of 30 bar outlet pressure to the reactor to enhance the conversion.

The product flow rate determines the economy of the running plant and, hence this factor is responsible for profit maximization in the plant. Reboiler heat duties of the two distillation columns determine the total energy consumption of this plant and hence minimizing this is important to save energy. Minimizing venting is equally important in a plant to reduce environmental damage. Our objective is to determine the operating conditions, which will simultaneously maximize product flowrate, minimize reboiler heat duty and, also minimize the vent flow rate.

Fig 1. The VCM plant flowchart

Initial Simulation

The base case simulation was performed using the Aspen Plus software. Three components (ethylene dichloride, hydrogen chloride and vinyl chloride monomer) were defined in the Component-Specifications sheet. RK-Soave property method was selected in the Methods-Specifications sheet to represent the vapor–liquid equilibrium. This information was sufficient to run the properties test. In the simulation section, the VCM flowsheet is defined. ARGibbs module was selected from the Reactors module, in order to explore the dependence of the product yield on reactor temperature and pressure. The feed and product streams were also inserted. A Heater model is inserted from the Exchangers module and the reactor outlet stream is fed to it. The heater outlet stream is fed to a RadFrac unit from the columns module, the bottom product of which is fed to another Radfrac unit. The product streams are inserted and the bottom product stream of the second RadFrac is recycled back to the reactor with a Pump unit from the Pressure Changers module. The reactor and temperature and pressure was optimized at 300K and 3 bar respectively. The feed composition and the operating conditions are specified as per the problem statement. (Refer to Fig. 1) The next sheet to be completed was the Reactions sheet. Nevertheless, no available reactions were selected because they were defined in the Reactions folder. Once the Reactions folder is opened, a new reaction pack is defined, and an ID was assigned to it. Once the reaction has been defined, the reaction was now selected and sent to the Selected reaction sets box. After loading all the required information, the Run button is pushed to start the simulation. The VCM yield achieved for the base case simulation was 85%.

Table 1. Sensitivity analysis- parametric optimization

VARY in Sensitivity Module	Base Case Value	Lower Limit	Upper Limit
COOLER (DEG SUBCOOL) (°C)	10	5	15
RADFRAC1 (MOLE RR)	1.082	0.8115	1.3525
RGIBBS (TEMP)(°C)	500	375	625
RGIBBS (PRESS)(BAR)	30	22.5	37.5

Analysis

During a sensitivity analysis (or design spec) Aspen iterates its calculation sequence through a range of values provided for an independent variable, in order to obtain a specified result for a dependent variable (within a certain tolerance). A complete sensitivity analysis was done using the ‘Sensitivity’ module of Aspen Plus to find out the impact of temperature and pressure of the cracking reactor, degree of sub-cooling of the cooler, reflux ratio of both the distillation tower on product flowrate, heat duty of reboiler and HCl vent flow. Parametric optimization was performed by changing the parameters to $\pm 50\%$ of its base case value. A design spec was also introduced to maintain the product purity of VCM to 99% (more than requirement), so that product purity is not compromised in any of the cases. The reflux ratio of the first RadFrac was selected as a manipulated variable for the Design Spec, and its value was varied by $\pm 50\%$ of its base case value. At the same time, three contradictory objectives were tried to be met: (i) Maximizing product flowrate; (ii) Minimizing total heat duty; (iii) Minimizing vent. For each manipulated variable, five number of data points were chosen at equispaced intervals. A total of 625 data sets were generated using sensitivity analysis in Aspen Plus. Plant data was not available and hence sensitivity analysis of Aspen simulation was used to generate the required data. The varying of parameters took into account the various process disturbances in an actual plant. A table showing the range of manipulated variables in the Sensitivity module is depicted in **Table 1**.

Artificial Neural Networking Modelling

Fig 2. Schematic of Artificial Neural Network structure

Artificial Neural Networks (ANN) are biologically inspired computer programs designed to simulate the way in which the human brain processes information. ANNs gather their knowledge by detecting the patterns and relationships in data and are trained through experience, not from programming (black box). ANN is formed from hundreds of single units, artificial neurons or processing elements (PE), connected with coefficients (weights), which constitute the neural structure and are organized in layers. As of now, no mathematical model of an industrial VCM plant is available. It is not possible to deploy a first principle based model as a real-time application with varying industrial conditions as it is time-consuming. However, a black box model is dependent on the quality of data. Only accurate measurements will ensure effective model. So, here we have used the data generated by sensitivity analysis in Aspen Plus to develop our model. Using the application tool of Artificial Neural Networking in MATLAB software, a model is developed which consists of four input layers, ten hidden nodes and three output layers. The input matrix consists of the manipulated variables in sensitivity analysis, namely, degree sub-cooling of the cooler, reflux ratio of the first distillation column, reactor’s operating temperature and the reactor’s operating pressure. The output layer consists of our target variables namely product flowrate, total reboiler heat duty and HCl vent flowrate. The developed calculation model will be used in real time plant control.

From the graphs of actual vs predicted values (**Figs 4,5,6**), we can see that ANN has accurately predicted the value of the objective variables.

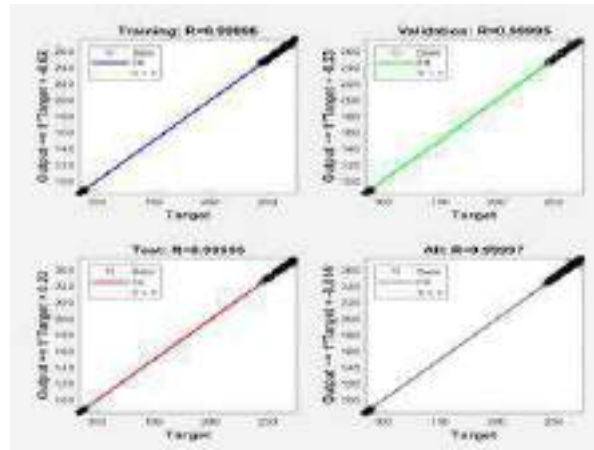

Fig 3. The regression coefficient of the developed ANN model

Fig 4. Validation of ANN model's predicted product flowrate

Fig 5. Validation of ANN model's predicted total heat duty

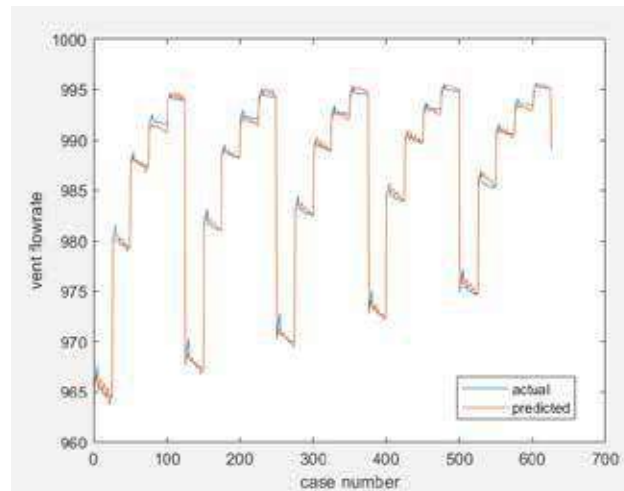

Fig 6. Validation of ANN model’s predicted vent flow rate

Five arbitrary cases were chosen within the range of the manipulated variables and the predicted values of the ANN model was compared to that obtained by Aspen simulation. The analysis is depicted in **Table 2**.

Table 2. Analysis of the developed model’s results

Description of Manipulated variables		
TARGET OBJECTIVES	Mean Square Error (%)	R2
Value		
Product (VCM) flowrate	0.06	0.995
Total reboiler heat duty	0.01	0.999
Vent (HCl) flowrate	0.035	0.998

The mean square error percentage obtained for each of the objective variable is less than 0.1%. The R squared value obtained for each of the objective function is above 99%. Thus, the model developed is highly accurate and reliable.

Multi-objective Genetic Algorithm Optimization

In computer science and operations research, a genetic algorithm is a metaheuristic inspired by the process of natural selection, which belongs to the larger class of evolutionary algorithms. Multi-objective Genetic Algorithm (MOGA) is a guided random search method. It is suitable for solving multi-objective optimization related problems with the capability to explore the diverse regions of the solution space. Here MOGA tool of the MATLAB software is used to optimize the VCM plant operation, which is modelled by using ANN, where the objective function is to increase product flow rate and simultaneously decrease total reboiler heat duty and HCl vent flow rate. Thus, we aim to find out the optimum operating conditions that will simultaneously meet the three contradictory objectives. The upper and lower limit of each target objective was set to the minimum and maximum value of the variable in the dataset generated. Through the conflicting objective functions a set of optimal solutions can be produced, and they are known as Pareto-Optimal solutions. These optimal solutions can’t say which one is better than the other with respect to all objective functions and the reason is that there are many optimality solutions. Also Pareto optimal set known as solution to multi objective optimization represent a collection of points. These solutions are also termed as non-inferior, admissible, or efficient solutions. There is no single optimum solution as the objectives are contradictory. This gives rise to multiple optimum solutions for simultaneously maximizing product flowrate, and minimizing heat duty and vent flowrate. It can be left to the operator’s discretion on which operating variable should be given more preference.

The trade-off between three contradictory objectives is depicted in the Pareto diagram (**Fig. 7**).

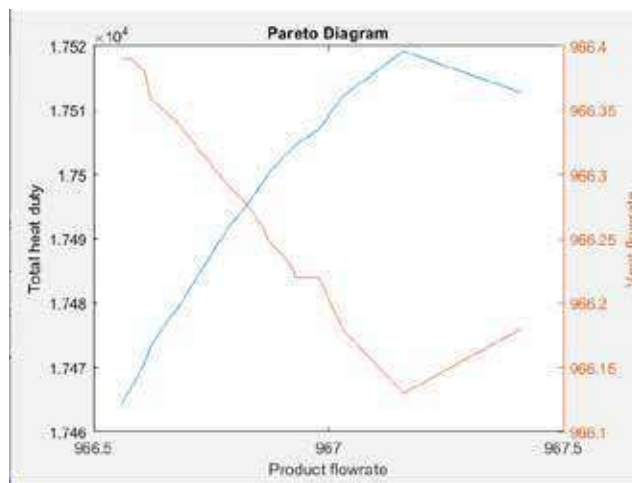

Fig 7. Pareto diagram depicting the optimal solution of the multi-objective optimization problem

The modelling and optimization framework developed can be deployed in a real time commercial plant to optimize the process parameters.

The optimum operating conditions obtained by the multi- objective Genetic algorithm optimization are depicted in **Table 3**.

Table 3. Optimal Operating conditions

S. No	Cooler Deg Sub-cool	Radfrac1 RR	RGibbs Temp (K)	RGibbs Press (bar)
1	5	0.81	375	22.5
2	5	0.81	425.03	22.5
3	5	0.81	425.02	22.5

18	5	0.8115	394.48	22.5

CONCLUSIONS

The developed modelling and optimization framework can be deployed in a commercial plant. The developed methodology is generic and can be extended to any other chemical plant. For the last few decades chemical industries have functioned with a single objective of profit maximization. On operating a plant with the philosophy of profit maximization, the chemical industries have damaged the environment drastically. It is only in the recent past, that the realization has dawned upon the industries

that they cannot survive in the long run by damaging the environment and there is a quest for finding a sustainable solution. Our study aims at finding a sustainable solution such that the profit is maximized and at the same time the environmental damage and energy consumption is reduced. Thus, finding a solution is a multi-objective optimization problem where we maximize the product flowrate but simultaneously reduce energy consumption and environmental damage by venting. This industrial case study has developed a modelling and optimization framework which can be deployed in a real, commercial plant for simultaneous achievement of three contradictory objectives such as profit maximization, energy consumption and environmental damage.

The developed methodology utilized the latest AI based modelling and nature-inspired optimization technique and is generic, which can be extended to any other running plant. The optimizer can be run on a real-time basis, and the optimal conditions can be evaluated in the ever-changing dynamic environment of the plant.

Artificial Intelligence Modelling for Real Time Prediction Of Melt Flow Index In Commercial HDPE Plant

Annasha Dey, Rhythm Aich, Dr. Sandip Kumar Lahiri

Department of Chemical Engineering, National Institute of Technology, Durgapur, West Bengal

✉ sandipkumar.lahiri@che.nitdgp.ac.in

ABSTRACT

In commercial HDPE plants, Melt flow index (MFI) is the most important quality parameter of the final polymer product. Usually, MFI is measured by lab analysis which takes 4-6 hours based on which, production engineers change the operating parameters to regulate the MFI. Due to this time lag, when product goes off-spec, tons of polymers are produced with undesired MFI value and industry incurs huge losses. In this work, a data driven model is developed from commercial plant data which can predict the MFI on real-time basis. Both of them are AI-based modelling methodologies. Improvements have been made to their basic algorithms to make them effective for accommodation of industrial plant data. Commercial plant data and plant operating experience has been utilised to identify the input parameters and train the models. The developed models are very accurate and reliable as evident from very high R2 value and very low prediction error percentage on unseen data (test data). The operating conditions obtained from both models have been compared against each other for further validation. These models can be deployed in plant DCS to indicate MFI of HDPE product in real-time basis which helps the production engineer to take easy corrective and preventive action to avoid losses from off-spec polymer product.

Keywords : Soft Sensor; Melt Flow Index; Artificial Intelligence; Artificial Neural Networks; Genetic Programming; High-density polyethylene.

INTRODUCTION

In our daily life, the usage of plastic in its various shape and size has become inevitable. The number of commercial plants for polymer production is increasing rapidly to meet the demand for plastic consumption. In a situation where the chemical industries are constantly providing for a gigantic consumer market, production of undesired products due to lack of knowledge, expertise or efficiency is highly unacceptable. Unfortunately, in most of the polymer industries around the globe, plants are run on the basis of experience only due to non-availability of reliable phenomenological model. The plant operator changes the value of operating parameters based on past experience which often doesn't lead to the most optimum conditions for production. This results in the production of undesirable products which eventually adds up to the waste generated resulting in huge losses for the industry.

One such major problem is faced by the operators working in commercial High Density Polyethylene (HDPE) plants. In the process of producing HDPE polymer, Melt Flow Index (MFI) is the most important quality parameter of the final product. Usually, this is measured using specially designed MFI apparatus in the laboratory. The lab analysis for calculating MFI of a polymer takes 4-6 hours for a certain range of temperature. Based on the results, the production engineers change the operating parameters to regulate the MFI. The major drawbacks of the lab analysis are it is highly time consuming and it only takes temperature as the variable eliminating the weightage of other variables that can be controlling the value of MFI.

The main objective of this project is to overcome this problem of inefficient testing procedures. Hence, an alternative way to calculate the value of MFI followed by the optimal range of variables responsible for governing it is desirable. Here, we have opted for data driven modelling so that it is possible to predict the value of MFI without a first-principle based model. The second objective of this study is to compare two different data driven modelling technique, namely Genetic Programming and Artificial Neural Network. Both of them are AI-based modelling methodologies and give results within a few minutes. The basic algorithm has been improved to accommodate the data of a HDPE plant and predict the value of MFI. The plant data will be used to train both the models and compare with the actual value of MFI. It is to see that which model is more accurate and reliable in calculating the MFI value. The R2 value and the error percentage of these models will be compared with each other.

The third objective of this work is to incorporate the best model in any HDPE plant and test its efficiency on real time basis

instead of waiting for lab results. The developed model can be deployed in plant DCS to indicate MFI value in real-time basis. It will be much easier for the plant operator to change the values of the input variables in order to produce polymer of the desired MFI value. This will save a lot of time and prevent losses to the plant caused by off-spec product.

AI-based modelling of MFI

The following steps were followed in developing the best model for predicting the MFI value.

1. Cleaning of the industrial data. It is important to clean the industrial data as the chances of anomaly due to reasons like malfunctioning of any instrument is very common. If those data are fed to any AI-based model, the model will not be accurate. So, the first step for preparing any data-driven model is to clean the data and get rid of dataset will abnormally low or high value of any input variable. There are total eight input variable and one output variable.
2. Preparing the Genetic Programming algorithm for feeding the data. This step is carried out in MATLAB. The entire dataset is divided into two parts, training and testing dataset. The training dataset is used to develop the model and the testing dataset is used to check the accuracy of the model.
3. MATLAB was used to build and train the ANN model. The Neural Network Toolbox is used to train, test, and validate the data. The user can manually change the number of hidden layers for this process and check the fitness for each of them.
4. After creating the models individually by GP and ANN, the result is compared. Trend of each variable is studied both for GP and ANN. The predicted value of MFI by GP and ANN is compared against the actual industrial value of MFI. Error percentage and accuracy of each model are considered.
5. Conclusions are drawn on which AI-based technique deemed to be the fittest for developing the MFI value.

Both the techniques are hit and trial method. So, the program is rerun several times until the fitness of the model (R^2) is maximized and the percentage error is minimized.

The details of all the input variables considered are given in the Table.

Table 1. Name of input variables

Input variable	Name of input variable
x_1	Hydrogen concentration
x_2	Reactor pressure
x_3	Ethylene concentration
x_4	Reactor Temperature
x_5	Reactor H ₂ to feed ratio
x_6	Reactor density
x_7	hydrogen flow
x_8	Reactor ethylene flow

Building the MFI model using Genetic Programming

Genetic programming is a biologically inspired machine learning method that evolves computer programs to perform a task. Genetic programming achieves this goal of automatic programming (also sometimes called program synthesis or program induction) by genetically breeding a population of equations using the principles of Darwinian natural selection and biologically inspired operations. It does this by randomly generating a population of computer programs (represented by tree structures) and then mutating and crossing over the best performing trees to create a new population. This process is iterated until the population contains programs that (hopefully) solve the task well. It is a hit-and-trial method but at the end of each run, we get an equation that helps us to understand both the structure and parameters of the mathematical model.

In this work, the Genetic Programming system is built in a way such that it is compatible with taking the industrial input, run

the program, and gives a set of equations as an output along with their complexities.

There are five preparatory steps of Genetic Programming. They are as follows:

1. The set of terminals for each branch of the to-be-evolved program.
2. The set of primitive functions for each branch.
3. The fitness measure
4. Certain parameters for controlling the run
5. The termination criteria and method for designating the result of the run.

There are three execution steps of Genetic Programming. They are as follows:

1. Randomly create an initial population (generation 0) of individual equations composed of the available functions and terminals.
2. Iteratively perform the following sub-steps (called a generation) on the population until the termination criterion is satisfied:
 - (a) Execute each equation in the population and ascertain its fitness (explicitly or implicitly) using the problem's fitness measure.
 - (b) Select one or two individual equation(s) from the population with a probability based on fitness (with reselection allowed) to participate in the genetic operations.
 - (c) Create a new individual program(s) for the population by applying the following genetic operations with specified probabilities:
 - (i) Reproduction: Copy the selected individual program to the new population.
 - (ii) Crossover: Create new offspring program(s) for the new population by recombining randomly chosen parts from two selected programs.
 - (iii) Mutation: Create one new offspring program for the new population by randomly mutating a randomly chosen part of one selected program.
 - (iv) Architecture-Altering operations: Choose an architecture-altering operation from the available repertoire of such operations and create one new offspring program for the new population by applying the chosen architecture-altering operation to one selected program.
3. After the termination criterion is satisfied, the single best program in the population produced during the run (the best-so-far individual) is harvested and designated as the result of the run. If the run is successful, the result may be a solution (or approximate solution) to the problem.

To develop the MFI model based on Genetic Programming, the training and test dataset is divided. In this work, $80 \pm 5\%$ of the total data has been taken as a training dataset and the remaining dataset was fed into the program as a test dataset. The dataset is chosen randomly. This step is comparatively time-consuming than ANN method as the two different dataset needs to be fed manually. After each run, the value of R^2 for training and testing data is received along with an equation with the best accuracy. The value of the input variables in the test dataset is then put in the equation to find the value of the predicted MFI. The error percentage is calculated for the MFI value. The program is rerun several times to and the best model is chosen. The best model gives the highest value of R^2 and the least error percentage.

Building the MFI model using Artificial Neural Networks

Neural networks are computer algorithms inspired by the way information is processed in the nervous system. An important difference between neural networks and standard regression is their ability to learn. This learning property has yielded a new generation of algorithms. An ANN paradigm is composed of several highly interconnected processing elements, analogous to biological neurons that are tied together with weighted connections analogous to synapses.

Training a network consists of an iterative process in which the network is given the desired inputs along with the correct outputs for those inputs. It then seeks to alter its weights to try and produce the correct output (within a reasonable error margin). If it succeeds, it has learned the training set and is ready to perform on previously unseen data. If it fails to produce the

correct output it rereads the input and again tries to produce the correct output. The weights are slightly adjusted during each iteration through the training set (known as a training cycle) until the appropriate weights have been established. Depending upon the complexity of the task to be learned, many thousands of training cycles may be needed for the network to correctly identify the training set. Once the output is correct the weights can be used with the same network on unseen data to examine how well it performs.

Neural learning is considered successful only if the system can perform well on test data on which the system has not been trained. This capability of a network is called generalizability. Given a large network, it is possible that repeated training iterations successively improve network performance on training data, e.g., by “memorizing” training samples, but the resulting network may perform poorly on test data (unseen data). This phenomenon is called “over training”. The proposed solution is to constantly monitor the network performance network on the test data.

MATLAB was used to build and train the ANN model for this project. The software has a feature called Neural Network Toolbox which is equipped to generate Artificial Neural Networks with custom specifications for training the model set by the user.

On being provided with a set of input and corresponding output data in the form of a matrix, the tool divides up the data into training, test and validation sets. In the case of this study, the data was divided in the following composition-

Training – 70%

Test – 15%

Validation – 15%

Then the user is asked to provide the number of hidden layers that are to be introduced in the ANN model. The method to be used for the training can also be set by the user. In this case, all training can be done by the Levenberg-Marquardt method.

After that is determined, on hitting the ‘Train’ button, the tool trains an ANN model. The Training, Testing and Validation graphs are also displayed, along with the R² value. The closer the average R² value is to 1, the higher is the accuracy of the training. The trend lines on the graphs also give significant indications as to the preparedness of the model.

Now for this case, we have searched for the model with the highest R² value and the lowest percentile error. We have also tried to minimize the number of nodes, as a lower number ensures a simpler and cleaner model.

The error was calculated by comparing the model and the results it produced against a previously unseen set of data. A piece of code was written within MATLAB itself to compare the two, find the percentile error and generate graphs representing the error.

After a large number of trials and errors, by changing the number of nodes and training multiple models, multiple times, a satisfying value was reached in all these categories.

This particular ANN model was selected for further testing and comparison against the model mode using Genetic Programming.

Results and Observation

For ANN, after a large number of trails and errors, by changing the number of nodes and training multiple models, multiple times, a satisfying value was reached. The given tables show the best result obtained by training the ANN.

To obtain the error percentage a code has been written within MATLAB itself which determines the error according to the following formula:

$$\text{Error \%} = ((\text{actual MFI value} - \text{predicted MFI value}) / \text{actual MFI value}) * 100$$

ANN modelling result is shown in **Table 2**.

From very high R² value and low MSE, it is concluded that developed model is very accurate and learn the relationship between MFI and reactor operating parameters.

Table 2. ANN modelling result

No of nodes in the hidden layer	Best R2 value	Least percentage error	Algorithm used for training	Transfer function
6	0.998	2.36	Levenberg-Marquardt	Sigmoidal

For GP, the best run parameters, the best model, performance metrics for the model and the model properties has been obtained. The formula used is same as used for calculating error percentage for ANN model. The least percentage error has been calculated for the test set which is 3.8%.

The following tables shows the results obtained for the GP model.

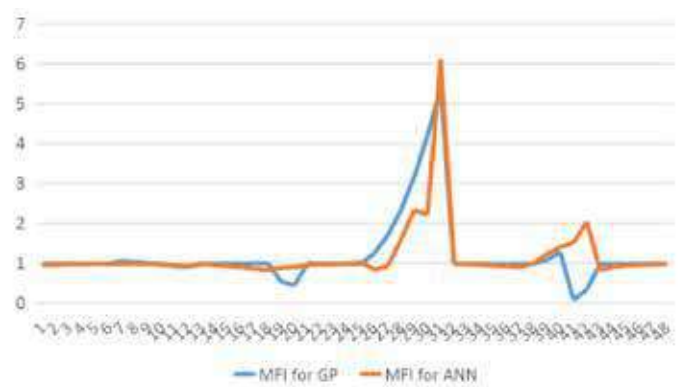

Fig 3. Comparison between the predicted MFI data for GP and ANN model

CONCLUSION

This paper develops artificial intelligence based modelling strategy to develop a relations between MFI and reactor operating parameters in running commercial plant. Such data driven methodology is easy to build and very accurate and very effective in scenario where phenomenological model is difficult to build or time consuming., ANN shows a better prediction accuracy than GP.

However, Genetic Programming has an advantage in the form that it produces a specific equation of the algorithm it has created

which can be further analyzed to understand the weightage of each variable in the process. This feature is unavailable in ANN as the closed form of equation is not available.

Developing model independently by two different algorithms (ANN and GP) increase their prediction reliability and reduce the false negative phenomena.

This complete methodology, when deployed in plant DCS, can almost instantaneously predict and show which variables to change and by how much to maintain MFI at its target range. This helps production engineer to understand to take necessary steps to maintain the desired MFI value and thus cut down on the losses due to off-spec product.

ABSTRACT

A simple time, resource, power and cost-effective solution is proposed for encryption and decryption of data block and the same method is proposed to be used for instruction encryption, which is stored in external RAM or cache memory. As this method is very simple to implement, so it can be easily implemented in software with single cycle operation e.g. no time delay and no extra HW resource is needed. The power consumption, processing power requirement and delay involved in this encryption-decryption process is close to nil, compared to other existing methods. These existing methods involve lot of delay, power and resource consumptions. So, the proposed method can be implemented in many applications, where data security is a concern without sacrificing the system performance.

Keywords : Cache memory, computer memory, embedded system, RAM, CPU, Hardware, Software .

INTRODUCTION

Today, due to widespread usage of data processing systems, there exists an inherent risk of misuse of confidential information. So, efforts have been made in the field of information security to improve the confidentiality, integrity, and availability of information.

A programmable computing unit is typically designed to process a sequence of instructions, which is referred to as program code to perform a certain task. In most common architecture, the program code is typically stored in a memory and supplied to the computing unit at runtime via cache memory. For information security purpose, it may be desired to protect the instructions from being analyzed while they are stored in the memory or transmitted from the memory to the computing unit. On the other hand, errors or malfunctioning may occur during an execution of the program code if the instructions reaching the computing unit differ from desired instructions. Differences between the instruction actually processed by the computing unit and the desired instructions may have a random cause or could be deliberately provoked by an intruder. So, it is desirable to store the data in encrypted form outside the CPU on the external RAM to avoid attacks.

There are two main kinds of attacks: snooping on a live RAM bus or modifying data on the bus and dumping the RAM content.

So, data encryption-decryption is always desirable for protecting data including the instruction in RAM. But the problem is most of time, the decryption process takes lot of processing power and imposes lot of delay in the process because of the reason as described below. So, today, most of time it is not feasible to apply encryption-decryption due to delay and extra processing overhead.

Generally, (as shown in **Fig. 1**) in each block encryption method, a secure key K_c (which is of N bit) is ExclusiveORed (XOR) with binary data block (D) which needs to be encrypted and produces a resultant data stream R . So, $R = D \oplus K_c$. On the decryption side, the reverse process is followed, e.g. the resultant data block is ExclusiveORed with the secure key (K_c) and the D is retrieved back. $R \oplus K_c = [D \oplus K_c] \oplus K_c = D$.

Where, \oplus denotes the exclusive OR (XOR) operation. This operation is sometimes called modulus 2 addition. The XOR operator is most commonly used as a component in more complex ciphers operations.

PROBLEM ASSOCIATED WITH THE EXISTING METHODS

Now, the ExclusiveOR operation- over N bits (N is key length), is very processing cycle expensive operation. As it imposes lot of delay in the system and consumes battery power and consumes lot of processing power. So, it is most commonly implemented in dedicated Hardware block. This makes the system expensive, difficult to interface with software, power hungry and slow (e.g. delayed). So, in many cases, though system designers wish to implement a secure mechanism for data protection

at every stage in data/information flow, but due to this above issue it is not feasible to implement.

As a reference- in one research paper [1], it is mentioned that - "...In principle, the entire encryption process for any given character requires 20 microcontroller clock cycles. Hence for the microcontroller running at 48MHz the time required for the encryption of a character is 0.42μ s...."

Fig 1. ExclusiveOR operation for Encryption / Decryption

DESCRIPTION OF THE PROPOSED METHOD

This solution proposes a simple, processing power, battery power effective, and resource effective method to encrypt and decrypt data.

In the encryption and decryption side there will be one random number generator, which will generate sequence of numbers [s1,s2,s3,...,sM]. The random number sequence generator is initialized with a SEED, which will be same as encryption side and decryption side and kept secret to both the parties. If the same SEED is fed in encryption side and decryption side random sequence generator, then they will generate same sequence of random numbers e.g. [s1,s2,s3,...,sM] Encryption_side will be same as [s1,s2,s3,...,sM] Decryption_side.

Now, in the encryption side, different bits located at different positions of the input data block (or instruction) are inverted based on the random number value. That means, if first number in the random number sequence is 6, (say, s1=6) then encryption block will change the bit value from 0 to 1 (or vice versa) at the 6th location of the 1st input data block. So, based on the random number, it just inverts the respective bit positions in the input data block (or instruction). Now, after the specific bit inversion, the input data pattern (or instruction) is changed, and which bit is changed that remains unknown to the eavesdropper/hacker. Repeat the same process over other input data block stream (e.g. instruction-2, instruction-3,...etc.) for encryption of the whole data stream (or whole program).

In the decryption side, it also generates random numbers using same SEED and that will provide the same random numbers (sequence of numbers) as produced in the encryption side. Here also, invert those specific bit values in the received encrypted data block (or instruction) at those specific bit positions, as indicated by that random numbers. That means, here also, the first generated random number will be 6 (s1=6), so invert the bit (0 to 1 or 1 to 0) at the 6th position of the received data block (or instruction). This will help to get the original data (or instruction) back. Repeat the same for other encrypted data blocks (or instructions) to decrypt and get back the whole data stream. Please find the details in next section.

This process does not require any XOR operations, neither requires any complex cycle intensive operations. It just invert the bit value (1 to 0 or vice versa) at some specific (secretly random way) bit positions, so it does not requires any resources – so offers very low cost, simple, power effective encryption-decryption solution with the same level of robustness as in existing with complex methods.

Fig. 2, proposed method of simple cost and resource effective data encryption and decryption.

Data Encryption Module

The following steps are performed at the data encryption side to encrypt the input data block (or instruction, e.g. one data block is considered as one input instruction). This is depicted in **Fig. 2**.

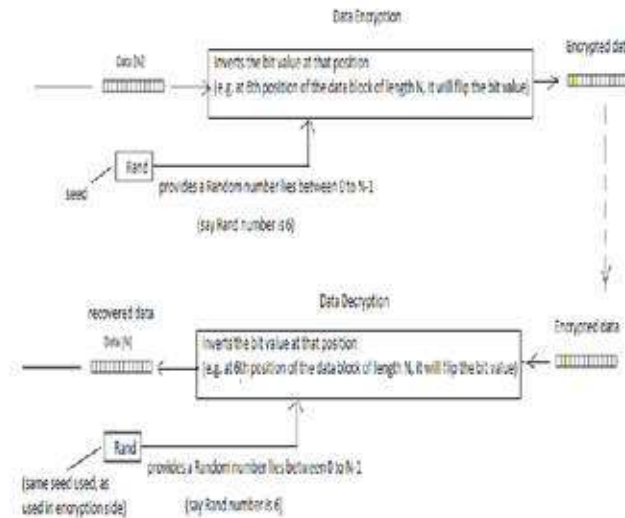

Fig. 2. Proposed method of simple cost and resource effective data encryption and decryption

Random Number generation

A pseudorandom number generator (PRNG) is an algorithm for generating a sequence of random numbers. This generates random number sequence based on the small set of initial values, called the SEED. A random seed (SEED) is a number (or vector) used to initialize a pseudorandom number generator. Two or more systems using matching pseudorandom number algorithms and matching seeds can generate matching sequences of random numbers which can be used to synchronize remote systems.

Here, we propose to use Rand () function, which is already available in the software and very simple to implement. The seed used here is also known to the decryption side, so that it also uses the same seed during reverse operation and generate the same sequence of random numbers.

In the encryption side, a Rand-1 () function is called and it provides a random number RN (from 0 to N) e.g. [s1,s2,s3,...,sM] Encryption_side . That means, the generated random numbers are: s1 is the first sequence, then s2 is the second sequence etc. till sM. Each random number lies in-between 0 to N value. Where N is the length of the input data sequence (or instruction max length).

Here, we assume that the first time generated random number is s1 = 6 (for example). Then ‘6’ (e.g. s1) number is passed to the next unit (data ciphering unit) for ciphering first input block (or first instruction).

Data ciphering unit

The input to this unit is: a random number from the rand-1 () and a data block of length N (or instruction). Now, based on the random number RN (say s1), the bit value of the Data [N] at location ‘s1’ is flipped. For example, say, the random number is 6 (say) and the data sequence is of length 8 (N = 8) is – 1010-1100. So, according to random number value 6, the 6th bit of the data sequence (1010-1100) will be flipped. Here, at 6th location the bit value is 0, so, this will be inverted, and the new value will be 1. So, the encrypted data block will be – 1110-1100.

Here, no exclusiveOR operation is performed, rather a random bit position is determined, and that bit is inverted. This operation can be done very easily without any processing load in software or CPU or HW.

One single bit change (inversion) over a data block (or instruction) is enough to protect that block, as the whole data block becomes garbled and cannot be recovered by a single bit change over a single block. If the data block size (0,...,N-1) is large enough, then instead of one bit position, several other positions can also be inverted using more rand() functions and then flipping those bit positions (in the same way).

This same process repeats over the other data blocks (or instructions) over the entire data sequence. That means, every time the rand function is called, which returns a number and based on that number the bit value at that specific bit location number of

the input data block is inverted as shown in **Fig. 2**.

Data De-Encryption Module:

The following steps are performed at the data decryption side to decrypt the data block.

Random Number generation

The decryption side also uses the same random number sequence generation mechanism that means it uses matching pseudorandom number algorithms and matching SEED. So, it calls the Rand-1() function and gets the same number as output ([s1,s2,s3,.....,sM] Decryption_side) as it was in the encryption side. That means, here also the Rand() will generate first number as 6 (say). This is passed to the next unit which is decryption unit.

Data deciphering unit

This unit receives the random number and the ciphered data block of length N (0,1,.....,N-1) as an input. Then it just does the reverse operation e.g. it just inverts the bit at the random number given position. For, example, here the input to the deciphering unit will be- the random number generated at first time which is 6 and the first input ciphered block data is 1110-1100. So, this unit will invert the bit value at the 6th position, which is now 1, that will be '0' once it is inverted. So, the de-ciphered data block will be 1010-1100. Which is the original bit sequence. So, we recover the original data block (or instruction).

Like this, the same will be repeated over the loop for the entire data sequence decryption.

ADVANTAGES OF THIS PROPOSED METHOD

The existing methods of data encryption-decryption uses XOR operations and are very complex to implement. Whereas this one proposes a new simple method which is not used earlier.

- (1) The proposed method of encryption and decryption is very simple to implement
- (2) It does not require any extra HW for doing ExclusiveOR operations, whereas the legacy methods require dedicated HW block for doing N XOR operations per data block, which makes the system more complex, resource intensive.
- (3) As the present method just inverts the required bit at a specific position (as indicated by rand) so, it is just a very simple operation and does not add any delay for encryption or decryption.
- (4) It does not take any extra cycles to implement the encryption/decryption.
- (5) It can be implemented by software only as it does not require any extra cycle intensive operations.
- (6) It can be used in several places to protect the data as using this process data encryption-decryption becomes very easy on both Encryption side as well as in the decryption side. So, transmitter and receiver encryption become very cost and resource effective.

POTENTIAL APPLICATIONS

It can be used in many blocks inside embedded and communication systems. Some examples are:

- (1) Secure code execution: The software/firmware code can be encrypted using this method (each instruction will be encrypted using this method). Then during execution, after fetching these instruction or data from external RAM or Flash memory, the processor will decrypt very easily using this proposed method without any cycle overhead and pass it to the decoder unit (in CPU). So, the instruction will be decrypted one by one (may be every block could be one instruction) and then passed to the instruction decoder unit in the CPU and then executed accordingly. This method will not impose the processing delay or power consumption overhead.
- (2) Communication system: In bus level transactions or data communication via wireless or wired channels can also use this same method for simple, resource, power consumption effective data protection.
- (3) Data storage security: The same also can be used for storing the encrypted data in memory and then later recover stored data using decryption.

CONCLUSION

Continuous efforts are made in the field of information security to improve the confidentiality, integrity, and availability of

information. But one major challenge is to implement a method which is simple, processing power, battery power, and resource effective to encrypt and decrypt data. But proposed method does not require any XOR operations, neither requires any complex cycle intensive operations. It just inverts the bit value (1 to 0 or vice versa) at some specific (secretly known random way) bit positions, so it does not require any hardware resources and offers very low cost, simple, power effective encryption-decryption solution.

Application of Artificial Intelligence for Intent Determination in Threat Evaluation

Development and Engineering, Network Centric System, Bharat Electronics Limited, Ghaziabad

✉ rahulmahajan@bel.co.in

ABSTRACT

The ability to identify intent of a threatening hostile aerial target is an important component of threat evaluation. Most of the current systems that have the capability of threat assessment employ mathematical models, which primarily compute threat on the basis of proximity and heading of a threatening track against a vulnerable asset. This approach proves quite reasonable as well as useful for these systems in intent determination [4, 8]. But sometimes an attacking aircraft may deceive the system by following a path that seems to be non threatening. This aircraft might be following an attack pattern before actually attacking its target. There is necessity to determine such threats following a predefined or new kind of attack pattern/profile along with its final target (vulnerable asset).

Keywords : Threat Evaluation, Machine Learning, Hidden Markov Model, Attack Profiles.

INTRODUCTION

Real time threat evaluation plays a vital role in a typical air defense scenario. In a tactical environment, an early and accurate threat assessment is vital to the defense of vulnerable assets. There has been a multi dimensional growth of air threats in recent times. A great amount of complexity in the environment is introduced due to presence of multiple targets and multiple attack profiles followed by these attacking aircrafts, and also multiple assets that are to be defended. [2-3].

As of now, Threat evaluation methodology adopted by systems has been mainly a rule based approach. The threat evaluation basically evaluates the hostile tracks in a real time environment for engaging these targets in a prioritized manner. Generally a set of rules are defined for determining the list of priority targets for engagement. These set of rules are limited to target kinematics and computations with respect to the defended assets. This approach has been used by many threat assessment systems [4] and has provided immense support to the ground operators in their decision making process to neutralize the hostile targets.

In recent years there has been a major shift from rule based systems to systems that involve intent determination aspects due to several limitations in rule based methods [1, 5, 6, 9]. These systems fail to incorporate the attacker's intent and tend to ignore different attack patterns adopted by the enemy aircraft for damaging vital assets. The need of the hour is to correlate the air track trajectory with attack profiles and find the defended assets for which the attack profile is being followed. System should have the capability to automatically learn from the three dimensional threat attack trajectory, identify patterns and predict the hidden intent which might not be perceivable in a real time air situation picture. This identification of attack profile is the core of Intent determination process. Profile matching in real time and efficiently in a dynamic environment for a large data set is the primary challenge in current scenario.

HMM APPROACH IN THREAT ASSESSMENT

In the current work we tackle the challenge of identifying attack profiles from track data based on HMM or Hidden Markov Model. HMM is a statistical model in which the state relationships between instants of time series are depicted by the hidden states transition

and the probability distribution between the hidden states and observations [9]. The modeling object in this approach is the track data consisting of feature vector with three attributes, namely speed, heading, and pitch. The main intent of the approach is to mine a reasonable description for parameter of the Hidden Markov model from the given dataset.

HMM contains the following parameters:

$$\theta = \langle O, H, A, B, \pi \rangle$$

Where $O = \{o_1, o_2, \dots, o_T\}$ is an observation sequence.

T is the total length of the time series, which in our work is the number of update cycles.

A hidden state set H consists of a finite number of discrete states. There is always a hidden state h_t belonging to H , corresponding to a certain observation o_t at time t , and all the hidden states are formed as a hidden state sequence. Matrix A consists of the transition probability between every two hidden states. The state transition probability matrix.

$$A = \begin{pmatrix} a_{11} & \dots & a_{1N} \\ \vdots & \ddots & \vdots \\ a_{N1} & \dots & a_{NN} \end{pmatrix}$$

Where $a_{ij} = p[h_i(t+1)|h_j(t)]$

i.e. probability of transition from hidden state i at time step t to hidden state j at time step $t + 1$. Again

$$\sum_{j=1}^N a_{ij} = 1, \quad \text{for all } i$$

If the observation distribution of a given hidden state is discrete, B is the measurement probability matrix. Otherwise, it is a conditional probability distribution function:

$$b_{jk} = p[o_k(t)|h_j(t)]$$

i.e. probability of emission of visible symbol o_k from hidden state h_j at time step t . Again

$$\sum_{k=1}^M b_{jk} = 1, \quad \text{for all } j$$

i.e. sum of the probabilities of emission of ‘ M ’ visible symbols from a given state ‘ j ’ is equal to 1.

We observe extracted feature vector in the target (track) dataset. The hidden state in our model denotes the motion trend of the aircraft. It cannot be directly observed through the saved flight trajectory. HMM solves this issue by computing the relationship between hidden states and observations. Obviously, the observation sequence is the feature vector in polar coordinates in this model. The hidden state set should be a finite set, and it needs to be manually specified.

The approach for identifying attack profiles can be summarized as shown in (Fig. 1).

Fig. 1. Determination of attack profile(s)

Dataset Preparation

The dataset preparation involves capturing of real-time track data following some attack pattern. The attack profiles that are to be used shall be labeled or shall contain metadata indicating a specific profile. Model shall use this data (and metadata) to learn characteristics of the profile. However one sample of each profile may not be enough. Multiple samples of each attack profile shall be required for the model. The real time track data mainly contains track information i.e. speed, heading and height.

The motion trend can be classified into three types (Fig. 2):

Speed

- Constant acceleration (A)
- Constant velocity (C)

- Constant deceleration (D)

Heading

- Turn left (L)
- Go straight ahead (N)
- Turn right (R)

Pitch

- Climb (U)
- Cruise (X)
- Descent (W)

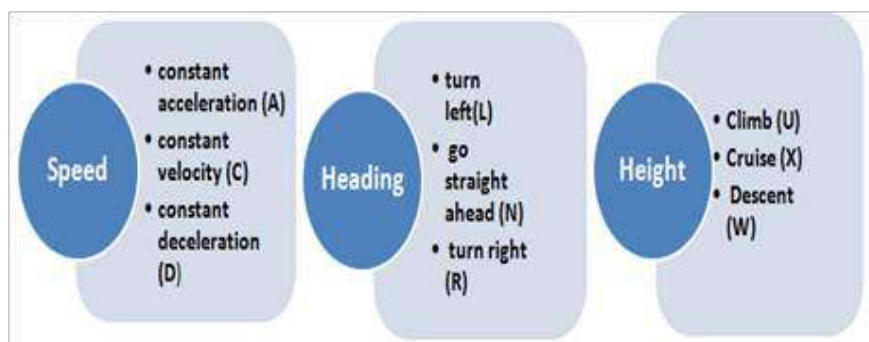

Fig. 2. Motion Trend

The approach uses these parameters from track data set namely, speed (constant, acceleration, deceleration), heading (left, right, straight), and pitch (climb, descent, or cruise). Based on track data set, sequence of trends (hidden state) i.e. <acceleration, straight, climb>, <acceleration, straight, cruise>, . . . , <deceleration, left, descent> are calculated as shown in figure 3.

These hidden state sequence are used for making transition probability matrix.

Let the speed unit be m/s, and the speed difference between two neighboring prediction time instants be $\Delta s = s(t+1) - s(t)$.

The trend of speed would be estimated by Δs ,

- $\Delta s = 0$ - zero means constant velocity(C),
- $\Delta s = \text{positive}$ - positive means acceleration (A), and
- $\Delta s = \text{negative}$ - negative indicate deceleration (D).

The heading is also calculated in similar manner as Δv ,

- $\Delta v = 0$ - zero means no change (N),
- $\Delta v = \text{positive}$ - positive means right turn(R), and
- $\Delta v = \text{negative}$ - negative indicate left turn (L).

The pitch is calculated as $\Delta \square$,

- $\Delta \square = 0$ - zero means cruse(X),
- $\Delta \square = \text{positive}$ - positive means climb (U), and
- $\Delta \square = \text{negative}$ - negative indicate descent (W).

Speed	Heading	Height	Speed (ΔS)	Heading ($\Delta \psi$)	Height ($\Delta \theta$)	Speed	Heading	Pitch
168.518	92.4441	9997	-44.059	11.3747	8001	D	R	U
212.577	81.0694	1996	8.417	-3.1563	0	P	L	X
204.16	84.2257	1996	14.045	-8.7523	0	P	L	X

190.115	92.978	1996	6.033	2.6632	0	P	R	X
184.082	90.3148	1996	4.718	-3.8701	0	P	L	X
179.364	94.1849	1996	0	0	0	C	N	X

Fig. 3. Design of State Transitions

Training Model

Based on the hidden state sequences, a transition probability matrix is generated. The final hidden state set of the motion trends has 27 members, each of which corresponding to one combination of speed, heading, and pitch from 3 speed×3 heading×3 pitch types. The hidden states are labeled as 1 to 27 corresponding to the indices of the elements in the hidden states transition probability matrix, so the dimensionality of the transition probability matrix is 27×27 since there are 27 hidden states in our model as shown in Fig. 4.

Fig. 5. Emission Probability Matrix

Once both the above matrix is generated, HMM model shall ingest them as an input for predicting the next or future sequence of activities (or states) from its previously predicted state as shown in Fig. 6.

Fig 6. Sequence of State Transitions in Dive Bombing

Profile generation and Matching

For predicting the most likely sequence of hidden states a dynamic programming algorithm shall be used. The efficient generate a path which is a sequence of states that generated the observations. In the profile generation phase, Concatenation of existing and predicted activities (future 50 activities) shall be performed to generate a new profile. This generated profile shall either match with some existing profile or treated as a new profile for the model. In this approach for performing matching of generated profile with existing profiles. The model shall accurately predict the attack type, probability of attack profile and the threatened defended asset (Fig. 7).

Validation

This trained model shall be applied to test the real time target environment which have not been used for training purpose and shall validate the performance of the model. The model shall be tested against multiple attack profiles that can exist in a real time environment.

SUMMARY/CONCLUSION

The approach used in this paper is capable of monitoring the air traffic and detecting out the anomalistic behavior indicating that deep learning models such as Hidden Markov models and rule-based classification may be a way forward in the automatic detection of attack profile of the aerial targets.

We have broken our central dynamic problem into several feature vectors to determine which state transitions are possible. This method can be used to describe the forms of relationships between speed, heading and pitch. All possible states in a system can be identified while offering a complete parameterization of all possible tactical maneuvers. Additional information can be used to establish which of the several alternative behaviors will actually take place. Performance of HMM based classification model may be enhanced by augmenting the existing training dataset with huge number of target profiles corresponding to each type of attack. Aircraft attack profile classification may be extended to various aircraft categories by training the model with the real or simulated track data corresponding to each category.

ABSTRACT

For large scale enterprises with multi-geographical presence changing their enterprise-wide applications is a daunting task, especially if the enterprises and their applications have been operating for decades. The application software having gone through test of time, passing through the hands of several developers have finally graduated to a level of maturity. The feature set enhancements, support to statutory and regulatory compliances and ensuring information security however necessitates continuous update and upgrades of the applications which also warrant the change in operating systems and middleware which further have a cascading effect requiring change of the underlying infrastructure. What becomes more challenging than update or migration of the applications is, to ensure that all these parameters are compatible with each other and that the applications availability is not hampered. To ensure that underlying infrastructure is capable of handling not just the sustained load but should be capable of handling the peaks as well. Some may out rightly propose ‘Cloud’ as the solution to the problem. However, establishing cloud too requires planning the underlying hardware. And, any miscalculation not only results in CAPEX loss but also results in OPEX when one seriously looks at the time and effort spent in managing the servers, storages, load balancers, operating systems and application. This paper proposes a data collection and analysis system for monitoring existing infrastructure, applications, resource utilization and database parameters to furnish real-time performance statistics & trend analysis to assist and simplify decision-making processes on capacity additions, upgrades of application & system.

Keywords : IT infrastructure monitoring, trend analysis, network monitoring, application Monitoring, System upgrades, etc..

INTRODUCTION

New features, regulatory compliances, threat intel feeds, middleware and database upgrades, Operating System updates and upgrades are some of the critical factors which force enterprises to update their enterprise wide applications. Similarly, as demand for the service increases, the need to enhance the capacity of their systems increases as well with view to have a well maintained and managed environment. Large scale applications have encountered resource problems when the load on the overall system becomes very large. Large levels of load can expose bugs (from application to operating system to hardware) that are only caused under these conditions. Multiple faulting components can destabilize the entire environment.

This seemingly simple action becomes mind boggling for those who actually have to perform these.

The major challenge which the system owners face is that at no point in time a situation of significant downtime is permissible. The applications should be available at time of need irrespective of the fact whether the applications are operating at 20%, 50%, 75%, 100% or even 150% load. The underlying infrastructure should be provisioned to provide necessary compute for all expected situations.

And, these are the question which the administrators, the architects as well as the developers struggle to answer. What are the expected situations wherein the applications are expected to operate? What should I size the infrastructure to meet the application requirement?

There is no readymade answer to these queries. Rather, the industry intuitively works on the experience of their best resources to size the hardware. And, this is what leads to resource crunch in few cases and over provisioning in most of the cases.

This paper provides a strong foundation for sizing the capacity upgrades. It proposes monitoring of existing IT infrastructure with smart trend analysis for determining the new size. The continuous monitoring of the applications, databases, operating systems, CPU, RAM and memory of the endpoints provides data whose analysis over a period of time in correlation with multiple events provides insight into the actual computational requirements of the applications at different loads and also forms the basis for predicting the compute required for an extrapolated loads.

BACKGROUND

Monitoring capabilities in health & performance tool keep a vigilant eye on the abnormalities occurring within the IT infrastructure. The server and application monitor allows one to set threshold limits for vital parameters that are important to maintain server uptime and to get instant notifications if the thresholds are violated. In addition, one can automate remedial actions such as starting or stopping a server or drill down to the root cause of the issue to understand and resolve them thoroughly.

Integrated health & performance tool's server performance monitor offers numerous analytically capabilities to measure and track resource utilization and their performance trends of infrastructure. While Trend Analysis reports [1][2] allows admin to understand the performance trends of different parameters in a end points. The health and application monitor enables one to plan load distribution and resource allocation adequately by providing capacity planning reports [3] that facilitates admin in identifying servers that are over-utilized or underutilized. Additionally, one can create custom reports and schedule automatic report generation based on set intervals.

Web-server-performance monitoring is an increasingly important field of research. Our review focuses mostly on existing soft-ware tools. One can find several techniques and methodologies to improve performances of Web servers by an appropriate software and hardware design in relevant textbooks. Monitoring a Web server is usually performed by analyzing its log files, which hold information about each single HTTP request and the consequent response and errors. According to the Common Log File Format, where the fields are filled with data coming from the request and the response. Given the high workload for popular Web servers, log file sizes can quickly grow to hundreds of megabytes. Log analyzers must present aggregated data so that they effectively represent a snapshot of the server's behavior and functioning over a given time interval. Several popular monitoring tools [4] exist, including Stephen Turner's Analog, Boutell. Com's Wusage and Maher Consulting's Access Watch provide a variety of parameters and statistics that are visualized using graphical interfaces. They aggregate monitoring data to inform Webmasters, for example, which pages in the Web site are the most popular, which countries (domains) are accessing the site, which pages outside the site contain broken links to pages in the Web site, and so on. The need for integrating several views of the log file motivated researchers to add a third dimension to graphical representation. Developed three different display metaphors for performance data time tunnels, scatter cubes, and geographic displays.

Currently various type of end point monitoring and performance analyzer tool [5] [6] were used for performance & health monitoring. In these tools monitoring may be configure either in agent based or agent less, but in large organization both type of monitoring is required. For monitoring of all end points, the separate monitoring tool was implemented. Both type of system have their own fault detecting and resolving technique which is completely different and management of each system is unique. There were no single integrated trend analyzer tool is available which may cater the trend analysis for computing resource utilization and application availability analysis.

SOLUTION APPROACH

In this paper we propose integrated trend analyzer of applications and computing resource of IT infrastructure which helps in system and application upgrade. In this approach we are monitoring IT infrastructure entity, end points resource utilization, applications & database health that helps to analyze real-time performance statistics & trend analysis. The monitoring of IT infrastructure may be done through agent based and agent less (SNMP based). It may track critical metrics, availability of end points & identify the root cause of issues, and resolve them using IT work flow automation. The historical data helps to analyze performance and utilization trends. On the base of resource trends on CPU utilization, memory utilization, packet loss, availability, response time, and disk utilization which assists for decision-making. **Fig. 1** depicts the overall view of proposed solution. Figure 1 shows the there are different component in the proposed solution. Agent less monitoring server, Agent based monitoring server, custom event adapter, performance & event Data store & trend analyzer Server.

Agent less monitoring server collect health data through SNMP based monitoring. It collect the data as per the provided management information base (MiB). The monitoring parameter may be configuring with the threshold breach condition, fault generation criteria and polling interval on server for monitoring. The health data as per configured parameter is collected through the SNMP walk and the fault generated on these devices will forward to the event processor.

Agent based monitoring server collect the health data & performance matrix through agent installed on end points. Server may also monitor the process/service & Log for generation the fault. For monitoring the services/process admin have to make a policy to define the threshold breach condition, fault generation criteria and error details. The performance matrix contains the resource utilization of CPU, Memory, Disk, Network etc. he fault generated on these device will forwarded to the event processor further processing.

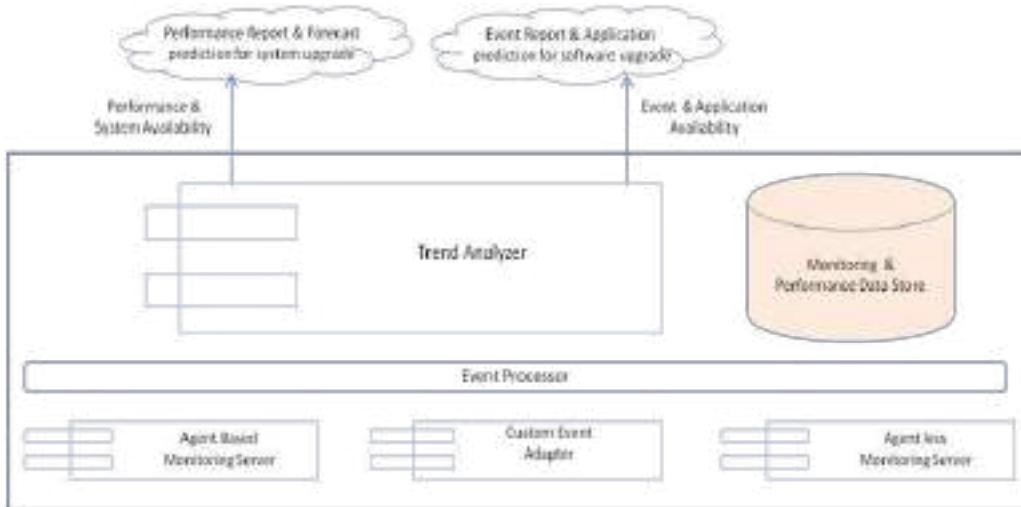

Fig. 1. Architecture of proposed Solution

Custom event adapter is used to integrate the event & performance data collected by other monitoring tools, which is seamlessly integrated and forwarded to event processor.

Event Processor is used for event categorization, de- duplication, event co-relation, alert generation, root cause analysis on monitoring data received from agent base monitoring server, agent less monitoring server & custom event adapter.

Monitoring & Performance data store keeps the data received from multiple monitoring source and forward all the data to trend analyzer.

Trends analyzer is the main component of the solution which collects the event generated from all the end points and the compute resource analysis data. These data are analyzed on the basis of different threshold, criteria and policies defined for application/system monitoring. The trend analyzer generates availability, performance and system utilization trends which helps in generating historical system performance, availability report and suggest/forecast on system resource usage for system upgrade/downgrade. The trend analyzer also generate the multifactor based application availability report and historical events trends for decision making for application upgrade.

EXPERIMENTAL RESULT

The solution is configured for more than 5000 agent based and agent less end points. these end points are different types, In agent based device servers, work station, laptop, tablet etc. and in agent less devices are radios, UPS, switch, UTM etc. these devices are configured in this environment for health status and fault resolution. In this experiment, an application is deployed on a server with recommended compute resource running 24*7. Here we have multiple cases for the trend analysis:

Case 1 : Trend analyzer shows that application has crashed 25 times in 1 month, when memory utilization has reached to more than 95%. So trend analyzer suggest to upgrade the system.

Case 2: Trend analyzer shows the compute resource utilization is not more than 50% but application has crashed more than 35 time in 1 month. So trend analyzer suggest to upgrade/downgrade the software version.

Case 3 : Trend analyzer shows the compute resource utilization is not more than 30% and application has not crashed in 6 month. So trend analyzer suggest to downgrade the system compute resource.

Case 4 : Trend analyzer shows the disk utilization is increasing at the rate of 5% per 20 days. In last six month disk space has crossed 60%(15% initial Use + 45 % incremental data). So trend analyzer forecast that in next 5 month disk will full so plan for upgrade the disk.

The trend analyzer also shows the multiple factor base health status & availability. The health status of end points shows the hardware status, utilization and trends as shown in **Figs 2-5**.

Fig. 2. CPU utilization and memory utilization trends

In the **Fig. 2** it shows that for a particular server the current CPU utilization trends which helps the administrator to decide that system should be upgrade/downgrade for a particular application.

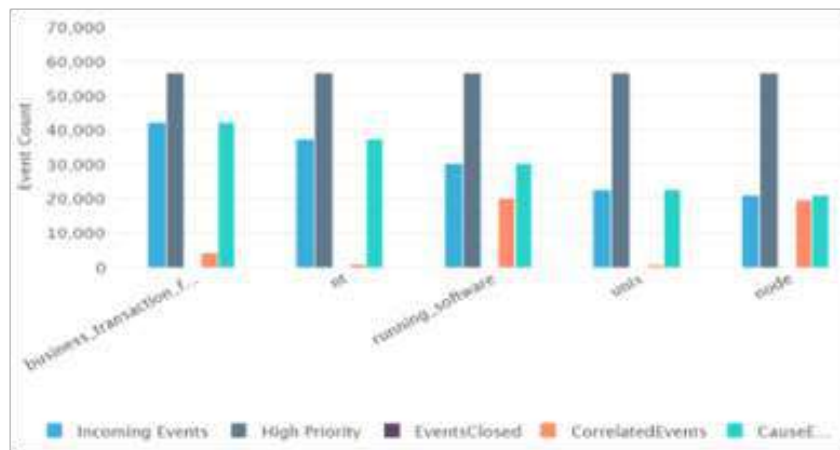

Fig. 3. Application wise CPU utilization

Fig. 3 shows the monitoring policy wise event count, which depicts the incoming events, high priority, closed event, and other parameter based events of different category.

Fig. 4 shows the application wise memory utilization, in which it depicts the usage percentage of memory trends for an interval for understand the usage pattern of memory consume by an application.

Fig. 4. Application wise Memory utilization

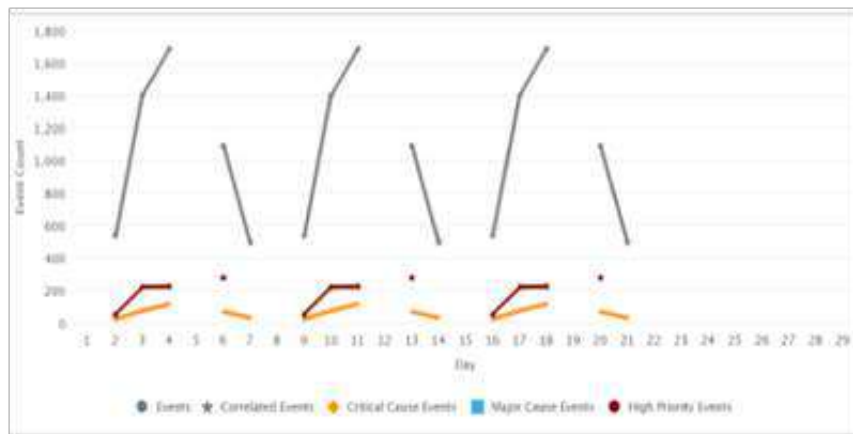

Fig. 5. Event distribution over time

Fig. 5 shows the event distribution over a time for analysis an application for resolving the faults and improve the up time or plan for new version of application.

CONCLUSION

This solution provides the performance metrics, Up & down time of end points & identify the fault issues. It also provides the historical data which helps to analyze performance and utilization trends. On the basis of the resource utilization, it assists and simplifies decision-making processes on capacity additions, upgrades, or maintenance schedules. It also provides the historical & forecasting trends for system and application availability with performance for deciding the system/application upgrade/downgrade.

Additionally, the future work may be entailed to include an AI module to predict application and / or hardware failures based on the historical data and watching the trends.

ACKNOWLEDGMENT

We would like to thank our Organization Bharat Electronics Ltd, our Unit Head and Executive Director, Mr Joydeep Majumdar and our Divisional Head Gp. Capt R K Dhir for giving us an opportunity to establish and work on the solution for IT infrastructure monitoring and for motivating and inspiring us. We would also like extend our gratitude to Mr. Amit Gupta and Mr. Manoj Tyagi for their unwavering support and guidance. We would also like to thank other members of our department for providing support in implementation of IT infrastructure as and when required.

ABSTRACT

Predictive Maintenance applications are gaining traction over the traditional preventive maintenance or run to failure maintenance activities in high availability mission critical systems. The advantage Predictive Maintenance has over the traditional methods is that it is trained on historical data related to a machine's state, operational behaviour and efficiency. Thus, a Predictive Maintenance application helps in carrying out effective maintenance activities, reducing maintenance costs and unexpected downtimes. This in turn helps in effective product lifecycle management. The Predictive Maintenance for Fire Control Systems is piloted in accordance with Defence Ministries' initiative to incorporate Artificial Intelligence (AI) in defence applications that aid the operator in effective Product Maintenance.

Keywords : AI; Machine Learning; Predictive Maintenance; Preventive Maintenance; Run to failure Maintenance.

INTRODUCTION

Equipment reliability and availability have been key cost drivers in manufacturing, especially when it comes to mission critical systems. For Defence Manufacturing industries, Product Support Lifecycle often extends up to a period of around 15 years. The traditional methods of maintenance such as run to failure maintenance, or preventive maintenance are based on Mean Time between Failures (MTBF) or Mean Time to Failure (MTTF) values for the devices during normal operating conditions. They do not take into account any abnormalities in the system. These typical maintenance activities can sometimes incur costs in the form of unplanned system downtime, high labour costs, high spare management cost. The method of Predictive Maintenance tries to overcome the shortfalls of traditional maintenance activities by constantly monitoring the equipment's operational behaviour and efficiency and estimate the maintenance period of the machine/system when needed[1]. A Predictive Maintenance method involves deploying a learned ML Model based on historical data to analyse the behaviour of the system, and warning the user of anomalous behaviour or predicting system/subsystem failure with reasonable accuracy. It also helps in just in time maintenance scheduling, thus avoiding unnecessary maintenance cost [2]. This paper describes the AI based Predictive Maintenance Piloted for the Fire Control Systems for Indian Navy.

PROBLEM STATEMENT

The Fire Control System is deployed in various ships of the Indian Navy. BEL has indigenously manufactured many systems/sub-systems/components for the Fire Control System. These assets need to be maintained for a period of over 10 to 15 years. There is a need to implement a maintenance method that shall further improve the systems' Reliability, Availability and Maintainability, and help achieve the goal of zero-defect performance.

SOLUTION

The proposed AI based Predictive Maintenance method consists of the following features to aid the operator in maintaining the system with minimal downtime.

- a) Real-time logging of operating hours and indication for the PCBs against the MTBF values.
- b) Provision to log PCB or item failures.
- c) Warnings and Anomaly Detection based on model prediction.

Given below is the flow chart of the steps involved from fetching of data to presenting the data on user dashboard.

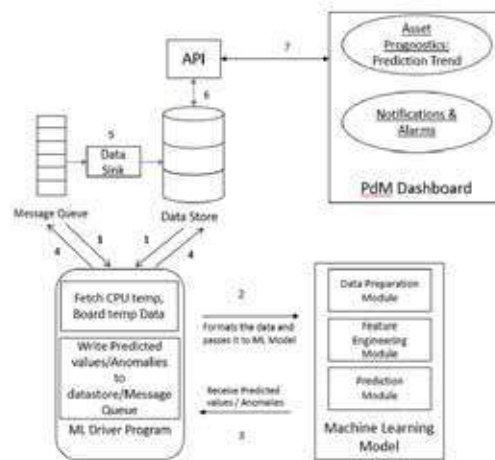

Fig. 1. Predictive Maintenance Flow Diagram

Step 1. Fetching data from Message Queues and Data Stores

The live data is fetched from Kafka Message Queue, and historical data is fetched from the Data Stores like Open Time Series Database (OpenTSDB).

Step 2. Data Formatting and input to ML Models The data fetched from Message Queue and Data Store is fed to the ML Model for further processing.

Step 3. Receive Predicted Measurements/ Anomalies The predictions from ML Model are fetched by the ML Driver program.

Step 4,5. Write Predictions to Data Sources.

The Predictions are written back to the Kafka Message Queue and OpenTSDB by the ML Driver Program

Step 6. Read Predictions, Notifications, Alarms from Data Stores

The Python API reads Predictions, Notifications and generated Alarms from the Data Store (OpenTSDB, Redis).

Step 7. Present Predictions, Notifications, Alarms on User Dashboard.

The Predictions, Notifications, Alarms fetched by the Python API are presented on the User Dashboard.

a) Real-time logging of operating hours and useful life remaining information for the PCBs against the MTBF values.

The proposed solution has a comprehensive HMI where the operator is made aware of the running systems with real-time logging and visualization of operating hours for MTBF based and life-limited based PCBs or items. The solution also incorporates user warnings based on percentage of useful life remaining for the PCBs.

Fig. 2. Dashboard depicting system health

b) Provision to log PCB or item failures

The operator is provided with an option to manually log the PCB or item failure. This logging aides in training AI/ML models for failure prediction.

Fig. 3. Failure Report Page

c) Warnings based on AI/ML models

Data was collected for various PCBs within the Fire Control System over a period of one year. The data was logged for the following subsystems: 1) Weapon data for large calibre gun mount. 2) Weapon data for low calibre gun mount (up to maximum of five gun-mounts) 3) Reference Voltages 4) Line to Line Voltages 5) Ship household data (Roll, Pitch, Speed) 6) Power Meter. This dataset was used to train and test the ML models for prediction and anomaly detection. We have used regression models for Prediction and supervised classification and unsupervised clustering models for Anomaly Detection. Given below is a brief explanation of the Regression and Classification approaches used for Predictive Maintenance of the systems/subsystems.

c1) Decision Tree Regression: Decision Tree Regression has been used to predict PCB temperature and warn user of anomaly in PCB temperature for various subsystems of the Fire Control System. The following are the steps followed:

Step 1. Feature Selection

We derived Start temperature as a feature for the PCBs board and CPU temperature variables. Start temperature is taken as the average of first 10 temperature values in each run.

Step 2. Model Selection

Decision tree regressor is used to predict Board/CPU temperature (continuous variable) using two other continuous variables (predictors) i.e. Message Send Count & Start CPU/Board Temperature. The hyperparameters used for Decision tree regressor are:

```

{“presort”:”deprecated”,
“ccp_alpha”:0.0,
“max_features”:null,
“max_leaf_nodes”:null,
“min_samples_split”:2,
“min_impurity_decrease”:0.0,
“min_weight_fraction_leaf”: 0.0}
“splitter”:”best”,
“criterion”:”mse”,
“max_depth”:10,
“random_state”:null,
“min_samples_leaf”:1,
“min_impurity_split”:null,

```

Step 3. Model Training and Validation

The model is trained on dataset after removing the abnormal data points, outliers and runs with less than 10 mins of total operating time. For training, the decision tree regression model has been fitted on 80% of historical dataset (2,68,654 observations). Cross-validation score is used to come up with optimum depth of decision tree model (10 in our model). By re-sampling the data multiple times, splitting them into training and validation sets, fitting trees with non-identical sizes on the training set and

looking at the classification accuracy on the validation set, the optimum tree depth has been decided, which gives the best bias-variance trade-off. One variable Message Send Count and one feature CPU/Board start temperature are used to predict CPU/Board temperatures respectively in the ML model as these predictors are highly correlated with response variable.

Step 4. Model Testing

The trained model has been tested on the remaining dataset (20% of whole dataset). For data splitting, train test split method of data splitting has been used which randomly splits the data frame into train and test subsets. The prediction accuracy of the Board & CPU temperatures is more than 97% and 95% respectively on the test dataset.

A smoothening factor has been added into the prediction data by calculating the exponential moving average (ema) of actual predictions. Given below is a sample graph of actual and predicted values for the PCB against vs Message Send Count.

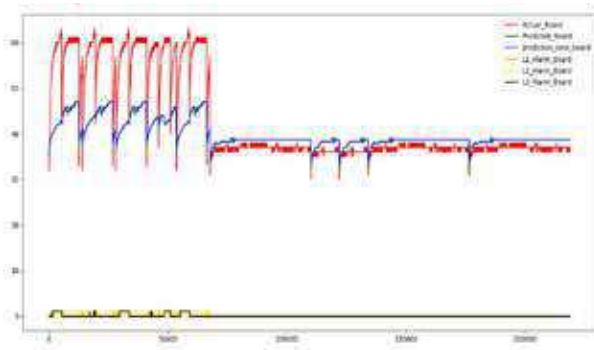

Fig. 4. Board Temperature (Actual, Predicted, Predicted ema) vs Message Send Count

Step 5. Model Evaluation

R-squared (r2) & RMSE methods of ML model evaluation has been used in this model. R-squared (coefficient of determination) estimates distribution of data points around the fitted regression line. A higher R-squared values represent smaller differences between the observed data and the fitted values. R-squared is the percentage of the dependent variable variation that a linear model explains. RMSE is a measure of the differences between predicted values by a model or an estimator and the values observed. Following is the model accuracy for CPU and Board temperature prediction:

Table 1. Model accuracy for CPU Temperature prediction

Alarm Level	Condition
RMSE	0. 8362605514574895
R2_SCORE	0. 9543043184746002

Table 2. Model accuracy for Board Temperature prediction

Alarm Level	Condition
RMSE	0. 5636338851667885
R2_SCORE	0. 9765438198557354

c2) Support Vector Machine: Support Vector Machine (SVM) has been used to classify and detect anomaly from input data for Power Meter. The Power Meter device provides the voltage, current and power values for various sub-systems of the Fire Control System. The scenarios identified for flagging anomalous behaviour are Lower and Upper Control Limit breaches, sudden jump in Power Meter values. The steps followed are:

Step 1. Feature Selection

A set of seven features was selected from a set of 200 parameters.

Step 2. Model Selection

The objective of our model is to classify a data as anomalous or normal. For this purpose, we have used SVM. The hyperparameter used are:

SVC(C=1.0, cache_size=200, class_weight=None, coef0=0.0, decision_function_shape='ovr', degree=3, gamma='auto_deprecated', kernel='linear', max_iter=-1, probability=False, random_state=None, shrinking=True, tol=0.001, verbose=False)

Step 3. Model Training, Testing and Validation

SVM Model was trained on 70% dataset and Testing done on rest 30% dataset. The logged data had more than 4 lacs data points. We resampled the data in batches of 600 seconds interval, and selected 95% of quantile to generate meaningful data (around 756 data points), out of which 530 data points were used for training, and remaining for testing the Model.

Step 4. Model Evaluation

SVM Model was evaluated by Kfold validation which gave accuracy of more than 95%. Given below is the validation measure and confusion matrix for the model:

Table 3. Model Validation Measure

F1 Score	0.9946
TPR	0.9985
TNR	0.95
PPV	0.9957
NPV	0.9827
FPR	0.05
FNR	0.0014
FDR	0.0042
Overall accuracy ACC	0.9947

Table 4. Confusion Matrix

Predicted Results	Ground Truth Table	
	0	1
	0	53
1	1	695

C3) Clustering:

K-Means Clustering algorithms is used to flag anomalous behaviour for the Discrete and Synchro PCBs. The Discrete and Synchro PCBs control the gun movement of the Fire Control System. The model flags anomalous behaviour whenever it identifies faulty sequences in the operation of systems and sub-systems. The faulty sequences are identified on the basis of patterns, sudden spikes and deviations from the ideal operating conditions. The steps followed are:

Step 1. Feature Selection

We selected 7 features from a set of 180 parameters. By using Principal Component Analysis (PCA) we reduced the dimensionality to 3.

Step 2. Model Selection

We applied multiple clustering algorithms to the dataset for identifying the most suitable algorithm [3]. First, the K-Means clustering was performed on raw dataset. The inertia value was very large due to high-dimensionality. Second, we performed K-Means after PCA. We plotted our PCA components to look for segregation. The clusters were overlapping. Third, we attempted Density Based Spatial Clustering Algorithm (DBSCAN) as data points were densely packed together. The hyperparameters Epsilon(eps) and minPoints were set to 0.3 and 10 respectively. The number of labels generated by the algorithm on 70 % train data was very large. Fourth, we attempted K-Means after PCA with normalisation. Based on the output of Elbow curve and Silhouette score, an optimum number of five clusters was selected. The model performance was found to be satisfactory.

Fig. 5. Optimized Clustering selection

Step 3. Testing validation and Results.

The model was trained on 70 % dataset and tested with rest 30 % dataset. Given below is the model accuracy in the form of Confusion Matrix and validation measure tables. The data visualisation in 5 clusters is also shown below.

Table 5. Confusion Matrix

Predicted Results	Ground Truth Table	
	0	1
0	21	1
1	3	36

Table 6. Model Validation Measure

F1 Score	0.9473
TPR	0.9230
TNR	0.9545
PPV	0.9729
NPV	0.875
FPR	0.04545
FNR	0.0769
FDR	0.0270
Overall accuracy ACC	0.9344

Fig 6. Data visualization in 5 clusters

RESULTS AND FUTURE SCOPE

The above results using a mixture of historical and simulated test data show the model accuracy for all the models to be greater than 90 %. As a Proof of concept, this Predictive Maintenance System will be installed in one of the Indian Naval ships. Further improvements shall be incorporated based on feedback from Navy and from our experience during integration with the actual Fire Control System.

CONCLUSION

Incorporating Industry 4.0 concepts such as Predictive Maintenance can help us in achieving higher Reliability, Availability and Maintainability (RAM) and thus a better Product Lifecycle Support for our Systems. Further, as BEL invests more and more in indigenisation of defence systems, extending the Predictive Maintenance to various projects can help in predicting failures and minimising downtime of these indigenous systems.

Leveraging Various Technologies for Tracking of Logistics in Steel Plants

Ayan Goswami*, Shyamalesh Saha

Research & Development Centre for Iron & Steel (RDCIS), SAIL, Ranchi, Jharkhand

✉ ayangoswami@sail.in*

ABSTRACT

In recent years, a rapid stride has been made in various technologies for tracking of logistics. Now-a-day various industries are increasingly employing these cutting edge technologies to track vehicles as well as materials to increase efficiency and production. During last decade, steel industry are extensively using latest technologies like GPS based, RFID based, Barcode and QR code based tracking solutions to track materials like slabs, coils, sheets etc. as well as transports like locomotives, dumpers, trucks etc. These has resulted in significant jump in efficiency of various operations in Steel Plants and minimised errors resulted from manual based tracking. The prime objective of this paper is to discuss various tracking solutions employed in Steel Industry for tracking of logistics whether it is raw materials, finished products as well as transports. This paper will emphasise on the various technologies, their usage and their applications in Steel Plant scenario.

Keywords : GPS; GPRS; Vehicle tracking system; RFID; QR Code; Logistic tracking.

INTRODUCTION

The importance of logistic tracking and tracing of raw materials, semi-finished products and end products are considered quite high for manufacturing firms like steel plants to ensure better customer service and also essential for managing logistics networks efficiently. Logistic tracking is one of the major problems faced by global industries both from tracking and tracing in their logistics supply networks, that creates huge coordination problems in the overall product development process[1]. Today's multi-supplier environments, manufacturing firms are looking for the appropriate solution to track their logistics, equipments, input & output materials, delivery shipment on real-time environment. In the last decade, rapid strides have been made in the field of various logistic tracking technologies. There has been an exponential growth in usage of these technologies for tracking logistics by various industries be it transports, railways, steel, mining etc. In today's world, there are several tracking technologies available to manufacturing industries through GPS, RFID, Barcode, QR Code etc.

Heavy industries like iron and steel industries are widely using these tracking technologies for tracking of logistics, be it raw materials, in-process products, finished products, in plant transports, locomotives etc. Each of the technologies mentioned above have its own merits and de-merits. All these technologies are finding wide applications in various areas of iron and steel making starting from raw material handling to dispatch of finish products.

The objective of this paper is to discuss application of various tracking solutions in the Indian steel sector. This paper will further emphasize on diverse usage of various solutions for tracking of logistics in steel plants.

GPS BASED TRACKING

GPS (Global Positioning System) is a radio-navigation system based on a network of orbiting satellites that send precise details of their position in space back to earth. The GPS devices on ground act as a receivers to the signals, and are used to calculate the exact position, speed and time at the vehicles location. The unique feature of this system is that it allows users to determine their three dimensional position, velocity and time anywhere in the world, be it land, sea or air. Like many other applications initially developed for military purpose, it is now being increasingly used for civilian purposes[2].

Integrated steel plants are heavily dependent on various modes of transportation like rail and road transport to ferry goods inside the plant. Generally, this transportation network covers the entire plant connecting all its major shops and locations, stockyards and dealers. Managing such a huge infrastructure poses a huge challenge to the plant. Smooth functioning of such distributed facility has a substantial impact on overall productivity of the plant. This traffic management can be eased and made more efficient and productive through the installation of a GPS-based vehicle tracking system. The vehicle tracking system employed in Steel Industry and in general have two major components:

- a) Vehicle tracking hardware
- b) Vehicle tracking software

Vehicle Tracking Hardware

In order to track vehicle in real-time, vehicle tracking system comprises of an in-vehicle device comprises of a GPS receiver and a communication module. The GPS receiver can be easily installed into the vehicle to be tracked. Its captures the GPS location information as well as other vehicle information at regular intervals and sends the information to a central server in remote location. Apart from geo-location, other vehicle information which can be send comprises of fuel quantity status, temperature of engine, altitude, door open/close, pressure of tire, ignition off status, headlight on status, taillight status, battery status, GSM area code, number of GPS satellites in view, emergency button status, total idling and movement status, odometer readings, engine RPM and vehicle speed, etc. to name a few. The efficiency of the GPS devices determines the effectiveness of the whole tracking system.

Most vehicle tracking systems, in addition to providing the vehicle’s location data, also provides a wide range of communication ports that can be easily hooked up with various controls available on board, allowing to check their status and control and help in automate their operation. **Fig. 1** shows the schematic of a GPS based locomotive tracking system.

Fig. 1. Schematic of GPS / GPRS based vehicle tracking hardware

Vehicle Tracking Software

The Vehicle tracking software essentially processes the data generated by GPS in terms of latitude, longitude, velocity and time for any given location. Huge amount of data is generated during tracking operation, which is transformed into relevant information. The vehicle tracking software can be broadly categorized into three modules, namely

- (a) Communication module,
- (b) Geographical Information System (GIS) module
- (c) Database Module.

The job of the communication module is to collect desired vehicle data either in real time or at a periodic intervals. GIS module relates to the digital map of the site, decode the latitude and longitude of the location received from the device and depict it over the digital map on the screen of the user in picto-graphical manner. Additionally, mapping of working location based on latitude and longitude can be saved into a database, which can be referred to draw display / mimic diagrams. The objective of the database module is not to store positional information and also to manage other information about vehicles, drivers, trips, GPS data loggers etc.

Fig. 2. GPS based vehicle tracking application software

Application of GPS based Tracking in Steel Plants

Now-a-day, GPS based vehicle tracking are increasingly finding its usage in steel plants. Some of the application areas are discussed here:

- Deployment of such a system in Blast Furnace (BF) zone of steel plant is briefly presented here. The tapping of hot metal from blast furnaces are done at pre-defined intervals. The liquid hot metal is transported to the steel melting shops in huge ladles called hot metal ladles. The ladle circulation time is a very important factor and on an average, it varies between 4 hrs to 7 hrs due to various operational constraints. Any deviation in turn-around time may eventually result in an increase in demand for more number of hot metal ladles and locomotives in circulation to compensate for the deviation. The GPS-based tracking system implemented for such hot metal ladles which are pulled by locomotives continuously provides the exact location of ladles inside the steel plant. This helps to plan the ladle movement from a central location. The major benefits due to such tracking systems are a reduction in ladle circulation time, lesser loco-run-hour, less amount of heat losses during the transfer of hot metal to mixer, etc
- GPS based locomotive tracking is increasingly being used for tracking locomotives in steel plant. locomotive tracking and fleet management of locomotives always pose a stiff challenge to the Traffic Department in Steel Plants. In-efficient fleet management results in significant delays resulting in high demurrage charges. Also, effective delay analysis becomes difficult and time-consuming without the availability of real-time data of locomotive movement. Hence, tracking of locomotives through GPS based tracking system is progressively being employed for managing a fleet of locomotives in steel plants.

RFID BASED TRACKING

Radio frequency identification (RFID) is a state-of-the-art radio wave based technology that enables simultaneous and automatic identification without the need for a line-of-sight. Based on the advantages of this technology, usage of RFID is spreading in various fields, such as smart card, localization, supply chain management, and so on[4].

Though various types of RFID exist, but broadly, we can divide RFID devices into two different classes: active and passive. Active tags generally require a power source. Active tags are either connected to a powered infrastructure like power supply or use energy stored in an integrated battery. For the second category of tags, the tag's lifetime is limited by the stored energy and depends on the number of read operations the device has undergone.

Passive RFID is very popular as the tags don't require batteries and are absolutely maintenance free. The tags also have a very long operational life. These tags are small and can be easily fit into an adhesive label and stick to the surface. A passive tag basically comprises of three parts (a) an antenna (b) a semi-conductor chip attached to the antenna, and (c) some form of encapsulation. It is the responsibility of the tag reader to power and communicate with a tag. The antenna of tag reader captures the energy and transfers the tag's unique identification. The entire operation is coordinated by the tag's chip. The encapsulation maintains the tag's integrity and protects the antenna and chip from environmental conditions, dust, chemical or reagents prevalent in harsh environment such as in steel plants.

In order to communicate, RFID tags and RFID tag readers have to be on to the same frequency. The most common frequencies an RFID system can use are as follows:

- Low frequency, or LF, (125 – 134 kHz)
- High frequency, or HF, (13.56 MHz)
- Ultra-high frequency, or UHF, (433, and 860-960 MHz)

Frequency Range	< 135 KHz (LF)	13.56 MHz (HF)	860-960 MHz (UHF)
Read Range	< 0.5 m	~ 1 m	~ 4-5 m
Tag Type	Passive Inductive Coupling		Passive or Active
Applications	Access control, Animal tagging, Immobilizer	Smart cards, Item-level tagging, Libraries	Supply chain pallet- box-level tagging, Toll collection

Table 1. Comparison of LF, HF, and UHF RFID

Application of RFID based tracking in steel plants

RFID based tracking is one of the most used technologies employed for tracking of materials / logistics in steel plants. Some of the applications are mentioned here:

- After manufacturing, the coil like HR or CR is packaged, banded, and kept in storage until delivered to the customer. Coils are generally very heavy, weighing over several tons. Therefore, cranes are used in plant for the coil movement. The coil information is being managed in following ways. First, a coil-storing map is used. When a crane moves a coil, information of the movement is captured and updated. Second, if there is a problem on the map, the operator have to check it by reading the marking or barcode labels attached to the coils. However, in case coils are marked manually or bar-coded, the workers have to come close to the coils to read the marking or the barcodes one by one. Therefore, the checking process is time intensive and can be very dangerous within the crane-operating boundary.

To address this problem, an RFID-based steel coil identification system is widely used these days. Unlike the barcode system, an RFID reader can read distant tags simultaneously without the need for an optical line of sight. Therefore, RFID tags are generally added to the label and attached on the coil which can be scanned without human intervention.

- The ladle running costs comprise not only the refractory costs, preheating fuel costs, and related labor costs, but also the cost of additional heating in ladle furnace due to lower than optimum ladle temperatures, consequently additional process delays incurred in delivering steel at the right temperature to the downstream unit, metallurgical disadvantages of receiving steel at caster at too low or too high temperature and the occasional costs of ladle breakout due to inability to judge the residual life of the ladle.

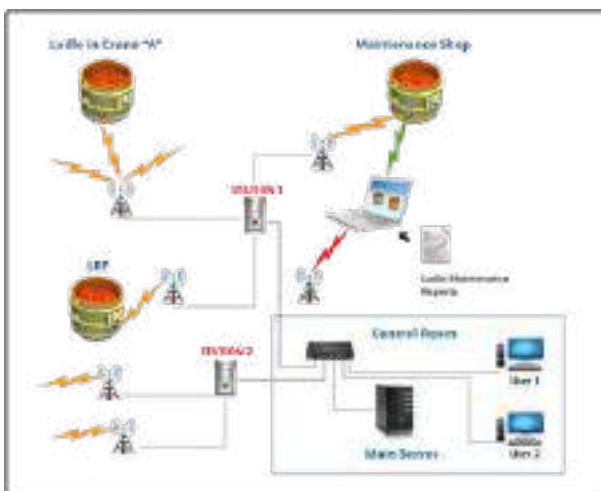

Fig. 2. Schematic of RFID based ladle management system

The RFID based Ladle Management is usually used to manage the complete ladle logistics in the most optimum manner in terms of energy loss, utilization factors. This has led to better planning of lining refractory which in turn results in a just-in-time supply of refractory materials. The temperature modeling has helped in better planning of target temperatures at various units (BOF, LF etc.).

BAR CODE & QR CODE BASED TRACKING

A barcode comprises of bars and spaces of varying width. It is basically an optical, machine-readable, representation of data wherein the data usually describes something about the object. The barcodes may be referred to as linear or one-dimensional (1D).

Similarly, a QR code is a type of matrix bar code or two-dimensional code that can store data information and designed to be read by smartphones and QR code readers. The QR stands for “Quick Response” which indicates that the content of the QR code can be decoded at high speed on the fly. The QR code comprises of black colored marks arranged in a square pattern on a white background. The information encoded may be text, URL, information, or any other data. The capability to put a huge amount of information in a small area and the ability to quickly decode the data has increased the popularity of QR codes. Its applications are growing rapidly all around the world.

Nowadays, barcodes and QR codes are increasingly finding their applications in tracking materials and logistics in the steel industry. Bar code or QR code stickers are attached to the coils, plates, etc. to identify them during different stages of its processing. Bar code readers and smart-phones are used to read these codes to determine the coil number. The readers are connected to the coil information system.

CONCLUSION

Various cutting edge technologies are increasingly being used for tracking of logistics as well as materials in steel plants now-a-day. These technologies have not only helped in accurately tracking of materials but also in effective planning and decision making in the steel plants. In recent times, machine vision, OCR based tracking etc. are also making its roadway into the logistic tracking and in future will change the way materials are tracked in steel plant.

Post-surgery Recovery using Deep Learning

Kuldeep Hule, Arjun Dashrath

Department of Computer Engineering, Army Institute of Technology, Pune, Maharashtra

✉ hulekuldeep@gmail.com; ✉ arjunsumant_19256@aitpune.edu.in

ABSTRACT

The objective of this research was to deploy a Deep learning, pose estimation algorithm by implementing an application that would analyze imperfections caused in fixing joints during orthopedic surgeries and provide corrective physical suggestions to fix improper joint placement/posture caused as a consequence of surgery. The application provides guidelines for optimal posture of multiple joints and prompts the user to imitate the movements consciously in order to physically fix the errors over time.

Keywords : Deep learning, Orthopedic, Post surgery recovery, Tensorflow, Pose estimation, PoseNet.

INTRODUCTION

Every year the world sees 22 million orthopedic surgeries. In India, 67% of the total orthopedic patients fall under 21-60 years of age, a significant part of the working population. 33% of these suffer from trauma that require corrective measures [3].

The most prevalent of orthopedic surgeries are:

1. Joint replacement surgeries (Shoulder, Knee, Hip)
2. Surgeries as a result of fractures, dislocations and muscle tears.
3. Spinal surgeries.

These surgeries usually have a long rest period for proper recovery but cause certain complications almost every time that require physical corrective methods for mobility and stance correction. The complications can be majorly divided into two categories:

1. The longer rest periods and prolonged usage of casts and braces often hinder the correct placement and structure of the injured joints.
2. Slight imperfections caused during surgery procedures that may deviate from the optimal joint placement angles.

For example, during an ankle surgery recovery, over or under pronation of the foot might occur due to the lack of pressure on the ankle due to long rest, weakened muscles due to long usage of casts and braces or incorrect attachment/positioning of the joint during surgery. This may have a permanent negative impact on the joint causing suboptimal physical capabilities of the joint or severe impairment.

The solution devised is to use deep learning algorithms to develop an application that analyses the joint placement and angles, compares it to the optimal structure from the existing dataset of optimal cases depending upon different body types and structures, finding the deviation from the optimal case and thereby recognizing incorrect surgery outcomes (incorrectly fixed joints) and incorrect stances (e.g. drooping of fixed shoulder) and suggesting corrective and medical solutions thereby making it ideal for professional and home usage. The corrective measure consists of guided stance correction that the user can consciously try to imitate to improve stance by strengthening muscles around the joints and getting habitual to it. For example, a spinal surgery may cause a patient's back muscles to be weakened due to bed rest causing a bad spinal posture, the application would point out the problem and suggest optimal corrective postures that the patient can imitate to correct their posture over time. Thus, the application can greatly contribute in post-surgery recoveries and incorrect surgery detection.

LITERATURE REVIEW

Pose estimation algorithms from various packages like Tensorflow and PyTorch have been extensively used in the past mainly for augmented reality, gait analysis and CGI techniques in movies.

A research was conducted in November 2017 by a group of American authors on NCBI USA on Artificial intelligence for analysing orthopedic trauma radiographs that used deep learning algorithms for diagnosing joint fractures and dislocations in radiographs. The results showed the algorithm predicting fractures with an accuracy of 83% [4].

Another research was conducted in April 2019 on Deep learning prediction on hip fracture using confounding patient and healthcare variables. Also, they were used statistical learning algorithms for finding a hip fracture [5].

Another research was conducted in March 2020 on PLOS ONE that deployed deep learning for analysis of bone quality in fractured osteoporotic patients. To investigate teriparatide action on parameters of bone quantity and quality and on Bone Strain Index (BSI), also derived from DXA lumbar scan, based on the mathematical model finite element method. [6]. In this research, Artificial Neural Network algorithm used for analyzing the various bone quality parameters.

TECHNOLOGY USED

Tensorflow

Tensorflow is an open source python library containing machine learning models that can be modified and redeployed. The applications will be based on the Tensorflow core version for x86 computers(windows/linux/macOS) and Tensorflow Lite for mobile phone platforms (Android/iOS) and arm-based computers/IOT devices (Raspberry Pi) [1].

Some examples of implementations of tensorflow are:

1. Google uses Tensorflow Machine learning models to optimize search engine results, mails etc.
2. PayPal uses Tensorflow implementations for fraud detection.
3. Coca-Cola uses Tensorflow to implement mobile proof-of-purchase

PoseNet

PoseNet is a tensorflow based vision model used for pose estimation, the algorithm used in the application would be similar to PoseNet with some extra additions to enhance the accuracy and the speed of the algorithm.

POSENET WORKING PROCEDURE

PoseNet detects human stances and connects multiple keypoints that can be used to detect angles between multiple key points [2]. The pose estimation happens in the following phases:

1. An input RGB picture is put through a convolutional neural network
2. A single pose algorithm using the bottom up approach returns a list of keypoints and its pose confidence score (the confidence of detecting a person/body part correctly). The algorithm detects multiple keypoints like elbows, shoulders etc. and returns their keypoint confidence score (the confidence of the key point being accurate)

PoseNet currently detects just 17 keypoints like shoulders, hips, wrists etc. which is insufficient for the application. Therefore, the implemented algorithm would contain more keypoints for each body part for higher accuracy and more recognition processes for poses of individual body parts along with the pose of the entire individual.

METHODOLOGY AND IMPLEMENTATION

Fig.1 showing application working flow.

The application would be connected to an optimal body angle data set (containing normal, healthy images of different body parts along with their angles to keypoints) for different categories of people (fit, healthy, etc.) and an issue data set (containing examples of errors caused due to incorrect surgeries or commonly occurring imperfections post-surgery) via cloud (AWS, Azure etc) and would be implemented as follows :

1. The RGB input picture will be selected or taken from the camera sensor and the user will select the body part to analyse (wrist, knee, spine etc)
2. The first process of the algorithm would be to detect similar body types to the user. For example, some users may be skinny while others may be healthier, the joint angles in the skinny users would be sharper due to less body fat while the healthier users would have softer joint angles

3. The algorithm would process recognition of the selected body part until a threshold confidence score is crossed
4. The algorithm will then determine multiple important key points that will be selected on the basis of the curvature of the body part and the goal will be to include maximum curve spots on that part until threshold confidence score is achieved to maximize the accuracy
5. The algorithm will then plot lines between the keypoints and store the angles between the indexed keypoints
6. The algorithm will then predict if the issue can be resolved by self-correction or will require surgical methods, it would inform the user of the latter and will state out the issues comparing to the issue dataset and terminate in that case
7. If the issue can be resolved by self-correction, the program will compare the angles to the optimal angles from the data set
8. The program will display a different coloured line indicating the optimal stance and will prompt the user to coincide the user's joint line to the optimal joint line until the lines are coincided thereby correcting the stance/joint posture.

Application will prompt to the users by reminding them to do this task frequently in order to the users for become habitual to the postures & develop muscle strength to maintain it, thereby improving the joint placement over time.

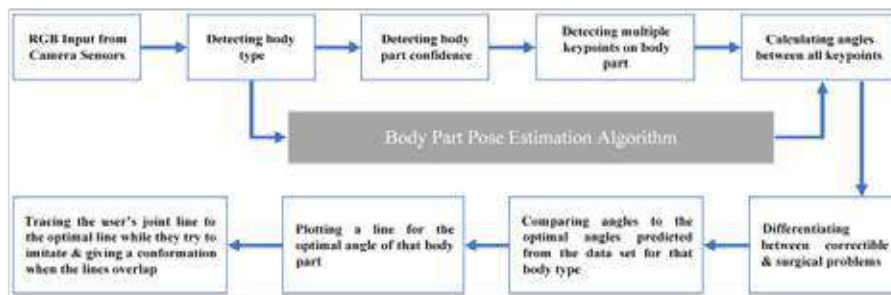

Fig.1. Application Flow Diagram

Figs 2, 3 & 4 will show some of the examples of application UI, in Fig 4 the green line signifying the optimal joint line to be coincided for correct posture(drooping shoulder).

Fig. 2. Example of keypoint mapping using PoseNet

Fig. 3. Optimal joint angles(shoulder)

Fig. 4. Optimal joint line to be coincided for correct posture

COSTING

Since there is no requirement for specific hardware, and the architectures being open sourced, no cost is required to develop the application. Storing the datasets in the cloud may require some additional costs. The most part of the expenses would come from developing the data sets according to the medical standards as it would require a lot of people to volunteer to help contribute to the images of the dataset.

FEASIBILITY AND CHALLENGES

Due to the vast support of Tensorflow over various platforms, the models are fairly simple to run on most devices and can be easily integrated on most application development interfaces/architectures. The challenge would be to develop such large datasets covering such vast categories of people and adhering to the optimal medical standards. The massive involvement of test subjects and medical professionals would require a great amount of effort. Moreover, storing and preparing such quantities of data would prove to be a challenging task.

CONCLUSION

Post-surgery recoveries have a bigger role in the patient's health than the surgery itself as the effects of an incomplete recovery can be severe and permanent like restricted physical capabilities, hampering movement or in worst cases, impairment. This study was focused mainly on modelling an accurate solution that could be used by the patients as well as medical professionals to avoid complications post-surgery and correcting the after effects of surgeries. The solution concluded from the study was to leverage such a deep learning algorithm to build a program that analysed the operated body parts and suggested physical and surgical corrective measures. The patients can self-diagnose their conditions and can consciously try to correct it with the aid of the application thereby reducing the risks of incorrect joint postures and positions due to weakened muscles. Moreover, doctors can confirm successful surgeries using the application by analysing minute imperfections that may go unnoticed to the eye and basic tests. Although it would be challenging to develop the datasets for the algorithm, implementation and usage of the application would greatly contribute to the field of surgery recovery and positively affect millions of lives all over the world.

Development of a Deep Learning Model for Analysis and Prediction of Sepsis condition

Melvin M, Banu Rekha B*

Department of Biomedical Engineering, PSG College of Technology, Peelamedu, Coimbatore, Tamil Nadu

✉ banurekha.cbe@gmail.com

ABSTRACT

Sepsis occurs while the body's internal fighting mechanism is activated against infections but it attacks the internal organs. It is a life threatening condition that can lead to localised or system-wide infection. Sepsis is difficult to identify at early stages, challenging the emergency and intensive care department. In this work, a Deep learning model is developed to predict sepsis condition before 11 hours of onset, that can aid the clinicians in early diagnosis and treatment planning. The dataset has been obtained from a public domain. The greatest challenge in this prediction model is the large number of missing data available in the dataset and the timing of prediction. While six hours or less is considered to be a golden standard for the prediction of sepsis, in this work, we have attempted to get the best possible accuracy for our method of data preprocessing. This foundational work can be explored and expanded with deep learning approaches to reduce the time window of prediction.

Keywords : Deep Learning; Sepsis; Long Short Term Memory; Imputation; Sequential classification.

INTRODUCTION

Sepsis is body's extreme reaction to an infection causing tissue damage, organ failure or death. It is estimated that globally, 31.5 million septic conditions arise every year [1]. While sepsis coexists with the existing medical conditions, it is necessary that sepsis is detected as early as possible to initiate antibiotic treatment. Hypotension is one of the outcome of septic condition and with hypotension conditions, the risk of mortality increases around 7% with every passing hour. Traditional clinical routines are ineffective in identifying the onset of septic conditions. Current research works carried out on vital signs data using machine learning techniques have explored the early identification of sepsis conditions.

In this work, the open source dataset of the clinical data collected from patients who underwent sepsis condition is considered. Due to the volume of data available, a deep learning method is attempted to predict the septic condition. The initial part of the research work focuses on detecting the missed data and performing the imputation. Using the data thus generated, we aim to develop a model to predict sepsis condition 12 hours ahead of its occurrence.

EXPLORATORY ANALYSIS OF DATA

The data was obtained from by Physionet repository. The Computing in Cardiology Challenge 2019 [2] was based on the database collected from patients who underwent sepsis condition. The dataset consists of 40,336 records with 40 various parameters of vital signs, laboratory test values and demographics. The exploratory data analysis performed on the dataset shows that the data is imbalanced with 7% of patient data labelled as sepsis and the remaining data labelled as healthy. The analysis of data also revealed the occurrence of a large number of missing data. Out of the 40 attributes, only 4 attributes, viz., Age, gender, HospAdmTime and ICULOS were void of any missing data. **Fig. 1** shows the percentages of missing data in the various attributes.

METHODOLOGY

The methodology followed in this research work is as follows:

- Exploration of the dataset
- Identification of missing data
- Imputation of missing data
- Training of deep learning model
- Validation of the trained model

Fig. 1. Visualization of missing data in the CinC2019 Sepsis dataset

Pre-processing of Data

The dataset is prone to missing values (NaN). To process and model the data, The features with less percentage missing data, less than 92% is taken. **Table 1** represents the count of missing data. This leads to reduction in dimension of data from 40 dimension to 10 dimensions, Heart rate, oxygen saturation, temperature, systolic blood pressure, diastolic blood pressure, mean arterial pressure, respiration rate, age and gender are considered. To process the missing data in the extracted features random sampling imputation is performed. Using mean or median imputation can distort the normal distribution of the data when a feature has more missing values. To predict sepsis before 11 hours of onset, the 11 data points before the diagnosis of sepsis condition are considered. The significance of random sampling imputation is illustrated on a patient sample with highest recordings.

Table 1. Features with number of missing value

Features	Number of NaN
HR	8
O2Sat	11
Temp	227
SBP	10
DBP	10
MAP	10
Temp	71

Handling of Imbalanced data

Data imbalance can be addressed in several methods such as Over-sampling, Under-sampling, SMOTE method. Oversampling leads to overfit the data resulting in high variance. Undersampling can sometimes lead to information loss and underfit the model.

Synthesized Minority Class Oversampling Technique (SMOTE) learns [3] the topological properties of the neighbourhood of those data points in the minority class. It generates the virtual training records by linear interpolation for the minority class.

These synthetic data are generated randomly selecting one or more K- nearest neighbours for each data point in minority class. The following plots is a scatter plot between two most correlated features with and without SMOTE.

Fig 2. Comparison with various imputation methods

Fig 3(a). Scatter plot of SBP and DBP before SMOTE

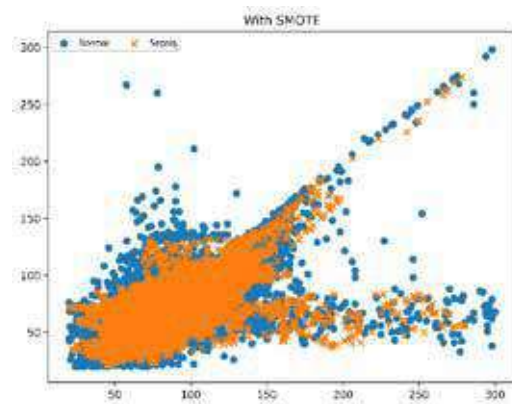

Fig 3(b). Scatter plot of SBP and DBP after SMOTE

SMOTE keeps the majority class (normal) data as much and over samples the minority class (sepsis) to the number of majority class by selecting the K neighbour data points in minority class, so the algorithm is less likely to over fit. **Fig 3** provides the effect of SMOTE on the data.

Architecture of the Learning Model

After pre processing and data augmentation the data is up-sampled to 59,740 files. The data was split as 80:20, 80% training: validation split. The input matrix of shape (47792,11,9) is fed to the model. Table II provides the features of the deep learning model.

Table 2. Model architecture

Layers	Nodes	Input shape	Output shape
LSTM	32	(None,11,9)	(None,11,32)
Dropout (probability=0.1)		(None,11,32)	(None,11,32)
LSTM	32	(None,11,32)	(None,11,32)
Dropout (probability=0.1)		(None,11,32)	(None,11,32)
LSTM	64	(None,11,32)	(None,11,64)
LSTM	64	(None,11,64)	(None,11,64)
Conv1D (kernel size=11)	64	(None,11,64)	(None,1,64)
Flatten		(None,1,64)	(None,64)
Dense	32	(None,64)	(None,32)
Dense	10	(None,32)	(None,10)
Dense	5	(None,10)	(None,5)
Dense	1	(None,5)	(None,1)

A combination of Recurrent Neural Networks and Convolutional Neural Network is used to train the data. The Recurrent Neural Network consists of 4 layers of LSTM stacked to fetch the temporal features in the time series data. The hyperbolic and sigmoid are used for activation and recurrent activation function respectively. Convolutions are useful to extract features with less trainable parameters. One dimensional convolution are used to reduce and extract information from each time step, ReLu activation is used. Three layers of Dense neurons are stacked followed by the convolutional layer. To avoid vanishing gradient ReLu is preferred as activation function. To predict the sepsis condition a neuron with sigmoid activation function is used.

Training of the Model

To avoid over fitting, two Drop outs each with dropping probability of 0.1 is inserted between the RNN. Kernel L2 regularization

is performed on all layers except the last neuron with regularizing parameter = 0.001.

The model was trained on 70,000 epochs with mini batch size of 64 samples, The model uses RMSprop optimizer with learning rate 0.000001 for optimization. The binary cross entropy is the loss function to be optimizer during training. Figure 4 provides the Training and validation accuracy and the corresponding loss.

Fig 4(a). Training and Validation accuracy

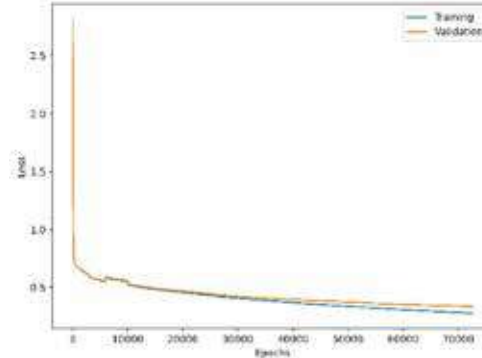

Fig 4(b). Training and Validation loss

RESULTS AND DISCUSSION

In this work, a total of 59,740 samples are augmented from 40,336 patients from which 47,792 samples were used as training set and 11,948 samples were used as validation set. The model achieves 92% of training accuracy and AUROC 0.92 for training set. Table 3 shows the metrics for the test data at the end of 70,000 epochs.

Table 3. Test data metrics at the end of 70000 EPOCHS

Accuracy	0.87
Loss	0.33
Precision	0.83
Recall	0.95
AUROC	0.87
F1 Score	0.88
Specificity	0.80

Recurrent Neural Networks can be useful in extracting features from time series data and Convolutional Neural Networks are useful in feature extraction. Instead of ensemble learning using different net within the same architecture yields good results. Fig 5 provides the performance of the deep learning model through the ROC and Precision-Recall values.

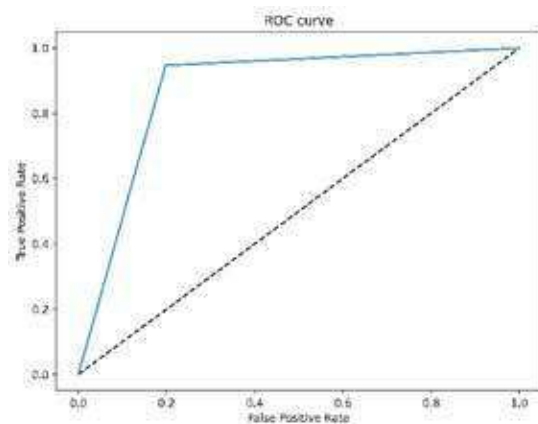

Fig 5(a). Receiver operating characteristic curve(ROC)

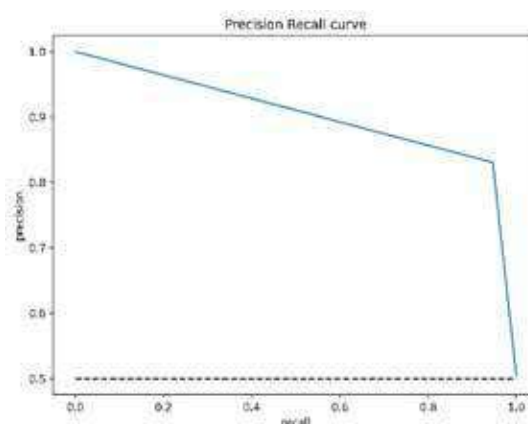

Fig 5(b). Precision recall curve

CONCLUSION

In this paper a model is developed which can predict the onset of sepsis before 11 hours. The model predicts good results even with uncleaned environment (missing values). The data processing pipeline can handle missing data and can predict sepsis in real time environment for early diagnosis and treatment. The model can be further optimized by hyper parameter tuning for better results.

Facial Expression based Pain Monitoring in Hospital environment using Compact Convolutional Network

Ashish Semwal, Narendra D Londhe*

Department of Electrical Engineering, National Institute of Technology, Raipur, Chhattisgarh

*✉ nlondhe.ele@nitrr.ac.in

ABSTRACT

Pain is a feeling of physical discomfort, and its assessment is known to be a crucial factor for medical diagnosis and pain management. Presently, subjective methods are used for pain assessment such as self-report which might provide inconsistent results. Therefore, several automated techniques have been proposed by the researcher in the recent past for pain assessment using facial expressions. However, current techniques for pain assessment utilizes very deep neural networks. Utilizing deep networks are prone to overfitting and computationally expensive. Therefore, in this study, a Compact Pain Assessment Network (C-PANet) has been proposed. To enhance the model performance first a VGG based deep model has been trained using an online pain dataset. Moreover, the knowledge of this network has been transferred to a much compact network. The compact network is consists of the Global Average Pooling (GAP) layer. Further, various data augmentation techniques are used to enhance the generalization of the implemented model. Further, we have also carried out extensive experiments to validate the proposed system. The proposed pain assessment system has been validated on a self-generated pain dataset of 10 patients recorded in the hospital. The experimental results demonstrate that the proposed method has achieved F1-score of 0.88 and AUC of 0.98.

Keywords : Patient monitoring; Deep learning; Computer vision; CNN; Fully Connected Network; network pruning..

INTRODUCTION

Pain is an unpleasant feeling and its assessment is very crucial for pain management and diagnosis of diseases. At present, subjective techniques are used for pain detection and assessment such as self-report and expert observation. However, such techniques are highly subjective and required proper communication between healthcare experts and patients. Hence, pain assessment based on self-report may provide inconsistent outcomes. Furthermore, in the case of infants and impaired patients self-report is not feasible. Therefore, in the recent past techniques based on objective methods are gaining more attention. In objective approaches, facial expression based automated pain assessment has been explored widely by researchers. This is because the facial expressions convey rich information related to pain[1]. However, previous pain assessment systems are trained on the dataset recorded in a highly constrained lab environment. Pain assessment based on facial expressions is still a challenging computer vision problem due to poor lighting conditions, variability in facial expressions, and partially occluded faces. Moreover, the current pain assessment systems are trained on the face images from the UNBC MacMaster dataset [2] which is collected in lab settings as shown in **Fig. 1 (a)**. It can be observed that the dataset contains high-resolution frontal face images. Moreover, the head pose is almost constant. The 2nd sequence represents the dataset collected in a hospital environment. Form the 2nd sequence it can be observed that there are high variations in head pose, illumination conditions. Moreover, the faces are not frontal. Because of the above-mentioned challenges pain detection is one of the challenging tasks in wild.

Fig. 1. Some of the images from a) the UNBC dataset b) self-created dataset. The yellow and red bounding box represent the corresponding head-pose

Literature Survey

Various research work has been carried out for pain detection using facial expression in the recent past. In this regard, the first work reported by Lucey et al. with the release of the UNBC-McMaster pain dataset[2]. They have trained an SVM classifier by utilizing landmark-based features. Further, Irani et al. [3] used separable steerable filters for pain detection. Further, Pedersen et al. [4] used a technique in which first faces are warp into frontal faces using AAM [5] and then a linear SVM has been trained. Nesov et al. [6] used SIFT features and trained SVM classifier for pain detection. Most of the previous approaches have utilized handcraft features with conventional machine learning techniques. Conventional machine learning requires carefully selected hand-engineered features which is time-consuming task. Therefore, recent works have utilized deep learning-based techniques for pain assessment due to their success in various computer vision applications[7, 8]. Given that, Zhou et al. has utilized RNN based network to learn temporal dependencies for pain assessment. A VGG-16 and LSTM based network is used for pain detection by Pau et al.[9]. Further, Bargshedy et al. [10] used a technique based on CNN-BiLSTM to classify pain intensities. The problem with the above-mentioned deep learning approaches is that they utilize a very deep network with a large number of trainable parameters. It has been observed that the deeper network has two main drawbacks; 1) problem of overfitting 2) computationally expensive. It has been observed [8] that a model with a large number of trainable parameters leads to overfitting. Moreover, the fully connected layer in VGG-Net increases the number of trainable parameters [11] which might affect the network performance. network pruning has been utilized widely in the recent past to compress the deeper model[12]. The layer-wise pruning is a technique in which the redundant layers are removed empirically. Therefore, in this study, a layer-wise pruning approach is utilized to compress the deep model. For this purpose, the author has proposed a GAP [13] based technique that can reduce the number of parameters in a CNN model. GAP based techniques are used in fully convolution network for localization[11]. It helps to reduce the parameters by taking the average of each feature. The compact networks might be useful for pain diagnosis in mobile devices.

The methodology has been described in Section I. Further, experimental details are presented in Section II. Section 3 described the results and discussion. Finally, the paper has been concluded in Section 4.

METHODOLOGY

In this section, we have presented the overall methodology of the proposed C-PANet for pain assessment. The overall methodology of the proposed pain monitoring system is depicted in Fig. 2.

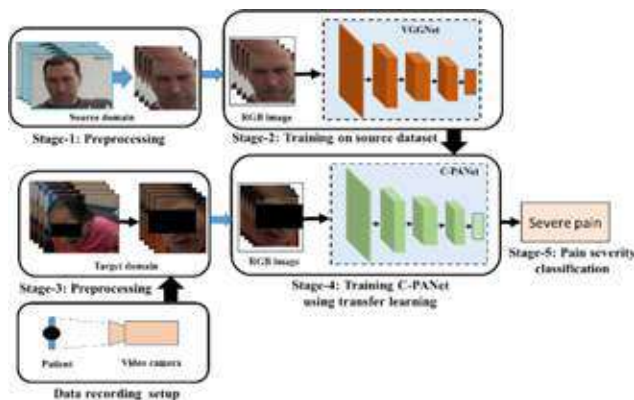

Fig. 2. The methodology of the proposed pain monitoring system

The methodology of the proposed system is consists of 5 stages. In the 1st stage, the face has been localized and cropped to remove the unwanted region. Further, a VGG-16 based network has been trained using the source dataset namely, the UNBC-McMaster dataset. In the 3rd stage, the face has been localized and cropped to remove the noise from the self-generated dataset. Moreover, the cropped faces are provided to a GAP based network by utilizing pre-trained VGGNet weights. Once the network has been trained the pain has been classified in the final stage. Note that the mode of training has been completed offline. However, pain monitoring can be accomplished using a trained C-PANet model.

Dataset Details

In this study, we have utilized 2 datasets. The first dataset is called the UNBC-McMaster dataset which consists of pain images of 25 patients suffering from shoulder pain. Moreover, a second dataset has been utilized which has been acquired at DKS

hospital Raipur C.G. India. The patient data is recorded by a Sony AX700 video camera. Before starting the video recording patient consent form and information sheet have been given to each patient. After that, the video of patients has been recorded for about 3 minutes duration. Moreover, the videos are annotated based on self-report and observation of the medical expert. All the video frames are then categorized into 4 classes namely, no pain, moderate pain, severe and very severe pain as shown in **Table 1**.

Table 1. Class-wise data distribution

Class label	Class name	Number of samples
0	No pain	11321
1	Moderate	3158
2	Severe	1460
3	Very severe	571

Preprocessing

In this work, we have employed face detection and cropping based preprocessing before training the proposed system. In order to detect face from input images, a multi-task CNN [14] based pre-trained model has been utilized. After detecting the face from input images each face has been cropped using their coordinate values (i.e., bounding box data).

Pain severity assessment using transfer learning

Deep neural network-based networks are generally trained using similar data distribution. However, in some cases, training data might be collected in different scenarios (i.e., using distinct sensors, different environments). This leads to a domain shift in the collected data which causes variations in the target dataset. Additionally, to train a neural network model large dataset is required to improve the model generalization. Transfer learning-based techniques are utilized widely in the recent past to alleviate such problems[9, 15]. Therefore, in this study VGG-CNN based source model has been trained on a larger dataset namely, UNBC-McMaster. Once the model has been trained the best weights are saved to utilize for transfer learning. For the second dataset, we have implemented a compact network namely C-PANet based on GAP. The C-PANet is a modified version of the VGG-16 network. In order to make this network compact some of the redundant FC layers have been removed. The Fully Connected (FC) layer at the output of the VGGNet has been replaced with the Global Average Pooling (GAP) Layer. It is worth noticing that the neurons in the FC layer are connected to a global region instead of the local region. As a result, the number of parameters in the GAP base network is significantly lower than FC based network. The architectural details of the proposed model are described in the subsequent section. The layer-wise values are presented in **Table 2**.

Table 2. Architecture details of proposed C-PANET

L. No.	Layer	Filter size	Output shape
L ₀	Input layer	-	(128,128,3)
L ₁	Conv1_1	(3,3)	(128,128,64)
L ₂	Conv1_2	(3,3)	(128,128,64)
L ₃	MaxPool-1	(2,2)	(64,64,64)
L ₄	Conv2_1	(3,3)	(64,64,128)
L ₅	Conv2_2	(3,3)	(64,64,128)
L ₆	MaxPool-2	(2,2)	(32,32,128)
L ₇	Conv3_1	(3,3)	(32,32,128)

L ₁₉	GAP	-	(512)
L ₂₀	Dense	-	(4)

Convolutional layer

The implemented model for pain assessment consists of 20 layers. The 1st layer of the proposed network is consists of a convolutional layer which has been represented by L1 as shown in Table II. A stack convolutional operation has been used along with ReLU and maxpooling to extract rich features related to pain. The convolution operation is calculated as follows:

$$Cn_{ij} = f \left(b_{ij} + \sum_{m=0}^{l-1} \sum_{n=0}^{l-1} (X_{i+m,j+n}) * W_{mn} \right) \quad (1)$$

where; Cn_{ij} = output of the first layer. b_{ij} = bias term, X = input matrix, W_{mn} = weights.

The stacked convolution has been performed for other layers by using (1). In our implemented network the number of filters has been doubled for each convolutional block. Note that convolutional operation with max-pooling extracts hierarchical features while the final layer (i.e., FC layer) is used for classification purpose.

Global Average Pooling (GAP)

Previous studies have shown that a network with huge parameters has the problem of overfitting[11]. Moreover, each node in the FC layer is connected to previous nodes. This leads to an increment in trainable parameters. Therefore, in this study, we are using the global average pooling (GAP) layer. GAP layer simply takes the average of each feature map and then the output is directly fed to the FC layer followed by the softmax layer. The problem of overfitting can be reduced using GAP since there is no parameter to optimize in this layer. Therefore, if there are spatial translations of the activations the GAP layer is more robust for that scenario. Once the network has been implemented the weight of the network has been updated using the backpropagation algorithm. The output of the softmax function provides different probability values for the final classification task. Since we have four classes a vector of four probabilities has been obtained. Suppose the probabilities are defined by p_1 , p_2 , p_3 , and p_4 for four classes. The pain intensities can be obtained as follows:

$$Y_{cls} = \operatorname{argmax}(P_1, P_2, P_3, P_4) \quad (2)$$

EXPERIMENTAL SETUP

In this work, to train the deep learning model Keras [16] library is used. Data loading and preprocessing has been done by the OpenCV [17]library. All the experiments are carried out in an HP workstation with an NVIDIA graphics card with 32 GB of RAM. In this work, 2 experiments are carried out. In the first experiment, the source model has been trained using the UNBC dataset. Moreover, in the second dataset, the C-PANet has been trained using transfer learning.

Before training the proposed networks for pain assessment, first, the images are resized to 128×128 . Furthermore, the dataset has been normalized between 0 and 1. Further, the dataset has been categorized into training and testing. For this purpose, 80 % of the data has been used for training and 20 % of the data is used for testing. Moreover, each model has been fine-tuned with 80 % of the training dataset using the stratified k-fold cross-validation technique. Finally, the held-out 20 % testing dataset is used to validate the generalization of the trained model. Note that after fine-tuning only the best weights have been utilized for the final prediction for the held-out test dataset. The learning rate of 0.0008 has been used for all the networks. Moreover, the batch size of 64 is used and networks have been trained for 30 epochs. Note that data augmentation such as rotation and horizontal flipping is used during training to improve generalization.

RESULTS AND DISCUSSION

In this section, we have presented the results of carried of experiments for pain assessment. Each implemented model has been validated using various metrics such as Precision, recall, and F1-score. F1-score is utilized to evaluate the model because it provides a better evaluation if the dataset is imbalanced. From **Table 3** it can be observed that the proposed C-PANet for pain assessment has achieved an average precision of 0.91 recall of 0.86 and F1-score of 0.88. From the evaluation metrics, it can be observed that the model has achieved encouraging results even in the challenging unconstrained hospital environment.

Table 3. Evaluation metrics for proposed C-PANET

Average	Precision	Recall	F1-score
Macro	0.91	0.86	0.88

Furthermore, to observe the effect of each class on the average performance, we have analyzed the class-wise performance of

the proposed system. From **Table 4** it can be observed that the class “0” which is no pain class has achieved Precision of 0.91 recall of 0.98 and F1-score of 0.94.

Table 4. Class-wise performance metrics of C-PANET

Class	Precision	Recall	F1-score
0	0.91	0.98	0.94
1	0.90	0.69	0.78
2	0.97	0.80	0.88
3	0.85	0.96	0.90

Further, we have analyzed the Precision-recall (PR -curve) curve for the proposed pain assessment system as depicted in **Fig. 3**.

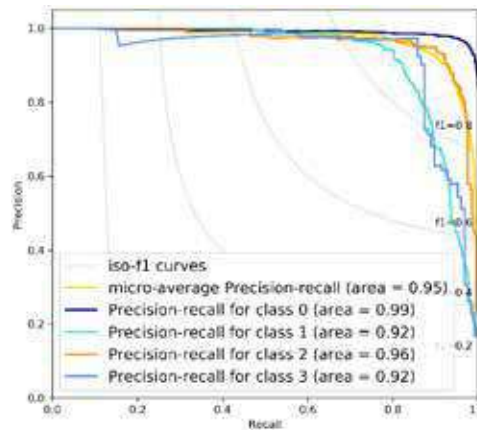

Fig. 3. Precision recall curve of the proposed pain assessment system

The PR-curve is a useful metric in the case of an imbalanced dataset. The trade-off between Precision and Recall can be represented by a PR curve using different threshold values. If the area under the PR-curve is high it represents high precision and recall. From **Fig. 3** it can be observed that for class 1 model has achieved PR value of 0.99. This indicates that the model can detect the no pain class accurately. However, the PR value for both moderate and very severe class the model has achieved lower PR values. The lower values of PR indicates that moderate and very severe class have less discriminative features.

Comparative analysis between GAP and FC based Network

To analyze the effect of GAP based model a comparative analysis has been carried out. To validate the effect of layer pruning two experiments are carried out. In the first experiment, the model has been trained using the FC layer. From **Table 5** it can be observed that the model trained with the FC layer has achieved a Precision of 0.92 recall of 0.86 and F1-score of 0.88. In our second experiment, the 2 FC layers have been removed and replaced by the GAP layer. As a result, the Precision of the network has been reduced slightly. However, the model has achieved comparable results. Additionally, it has been observed that the model trained with the GAP layer has reduced network parameters up to 14 %. Currently, the FC based network takes around 43 seconds to complete one training epoch, while the GAP based network takes around 39 seconds. This demonstrates that the implemented GAP based pain assessment model maintains a trade off between network complexity and performance.

Table 5. Comparison of FC and GAP based network

Class	Precision	Recall	F1-score
0	0.91	0.98	0.94
1	0.90	0.69	0.78
2	0.97	0.80	0.88
3	0.85	0.96	0.90

Comparative analysis with existing approaches

This section presents a comparative analysis of the proposed pain assessment system with existing approaches. Note that only recent works have been included in this study, for comparative analysis. To the best of our knowledge, the proposed system based on GAP based pruning has not been implemented previously for pain assessment. From **Table 5** it can be observed that

the work done by the researcher [2] have been used conventional machine learning technique which might fails if data size increase. Our proposed method has been trained using a fully automated method for pain assessment. Further, deep learning-based methods are used by [9, 10], but their implemented model has a large number of trainable parameters which might lead to overfitting and computation burden. From Table V it can be also observed that previous approaches are trained using the lab collected dataset. Such models might not work in unconstrained hospital settings for pain monitoring. Contrary, to previous work our pain assessment model, has been trained on challenging datasets acquired in hospital settings. Moreover, the proposed model has achieved F1- score of 0.88 and an AUC of 0.98. The encouraging results demonstrate the usefulness of the proposed pain assessment system in hospital settings for pain monitoring purposes.

Table 5. Comparative analysis of proposed method with existing approaches for pain assessment

Approach	Dataset	Metrics
SVM[2]	Lab collected	AUC: 0.83.9
CNNLSTM[9]	Lab collected	ACC:
BiLSTM[10]	Lab collected	F1: 0.89
C-PANet (ours)	Hospital dataset	F1: 0.88 AUC: 0.98

CONCLUSION

This work presents a fully automated pain monitoring system which can assess pain from face images. For this purpose, a compact CNN model has been proposed which utilized a pooling-based pruning strategy. The work demonstrates that the GAP based model not only reduces the computational burden but maintain the network performance of pain assessment. Further, we have also utilized a transfer learning approach to improve network generalization for the pain assessment task. The experimental results demonstrate that the model has reduced up to 14 % with about 1.0% loss in Precision on the self-created pain dataset. For the future other pain behavior parameters such as body movements and sound can be utilized with facial expression to improve the robustness.

ACKNOWLEDGMENT

The author would like to thanks the doctors at DKS Super Speciality Hospital Raipur for their valuable guidance during data recording. The author acknowledges the Science and Engineering Research Board (SERB), Government of India, for financial support vide Reference No. EEQ/2017/000470 to carry out this work.

Secured Approach for One Umbrella Management System for Improving Healthcare Services

Dr S Tamil Selvi, B Ganapathy Ram, V S Preethashree

Department of Electronics and Communication Engineering, National Engineering College, Kovilpatti, Tamilnadu

✉ stsece@nec.edu.in

ABSTRACT

People living all over the world are directly or indirectly connected with health care services for monitoring and maintaining their health care records. In case of emergencies, patients are required to get the hospital services through doctors, pharmacy and clinical laboratories. Sometimes patients need to know the availability of doctors, availability of medicines in a pharmacy and their clinical records after doctors' validation in a secured manner. Sometimes patients need to carry their previous clinical reports while consulting with doctors. With the deployment of One umbrella Management system (OUMS), it is possible to integrate the various stakeholders such as doctors, patients, pharmacy, healthcare industry to meet out their requirements. The proposed OUM system facilitates the patient and doctor to visualize the history of medical records at anytime, anywhere in the world with two layer security. Only the authenticated user could able to access their data with the help of secured encryption and decryption techniques. The proposed architecture enables the patients to access the various services offered by hospital management system, pharmacy and clinical laboratories with their digital signatures and certificates in a cost effective manner.

Keywords : Health care information system, Two layer data security, Data access control, OUMS.

INTRODUCTION

COVID-19 pandemic has thought the human about the significance of maintaining stable and good health condition to tackle and to combat with the viruses. Maintenance of health condition requires periodic health checkups, analyzing the health records and undergoing proper medication/treatment during unhealthy conditions. All the above-said processes are taken care of by hospitals or health care centres. One of the most traditional methods followed for maintaining health record is a manual method, which includes paper and files. It is a very difficult and high time-consuming process which often requires large storage space. Electronic health record (EHR) replaced paper-based record creation and maintenance by storing the patient's health information (PHI) in the database. The patient's health records need to be accessed easily at any time from any location and also make patient's to analyze their health conditions to lead a healthy life.

A healthcare management system should not only be computer software that provides facilities to manage the hospitals but also to support increasing the efficiency of healthcare services. The main characteristics of online HIS comprise many important decisions which may need artificial intelligence. Decision-making process in the healthcare management system should be fast and accurate.

EHR is a large amount of data, which is very sensitive and affects patients' privacy and security if misused. Digitizing patient health records is having a danger on another hand, which may be stolen or misused by various intruders like organ smugglers, insurance agencies, employers, any entity intended in exploiting the data for personal gain. Exchanging health records of patients between various stakeholders of the healthcare system by connecting digital technologies existing in the healthcare management system, which brings major concerns to maintain confidentiality and privacy on the patient's record. Security and privacy are more important in EHR as important as Quality of service (QoS).

As technology is growing fast and the penetration of information and communication facilities in the healthcare sector, the HIS is facilitated through mobile devices. Healthcare service providers as well as patients are using mobile devices, which causes security breaches on both sides of PHI. A security breach can be done in two different ways that are attacking the network and brute force attack on data related to HIS. Network attacking is controlled by installing and maintaining the strongest cyber security infrastructure, which may incur a large cost. Data access control solutions are only a smart move to keep health data as secure as possible. Hence, in this paper, the PHI is accessed with strong double-layer encryption using public and private keys, along with digital signature and certificate for secured data access control over the internet.

Rest of this paper is organized as follows. Section 2 deals with studies and analysis of healthcare information system developed or portrayed in various literatures. Proposed methodology is explained in the section 3. Experimentation with detailed specifications are represented in the section 4. Section 5 portrays the results and discussion on the research done for implementing the proposed data access control mechanism. In the section 6, conclusion is arrived and future scope is predicted.

LITERATURE SURVEY

In [1], a secured EHR system is developed to track and monitor the health condition of the patient in order to make prior decision to avoid chronic disease. In addition, it reduces the patient's time to consult with healthcare providers. The ultimate objective of this paper is to provide quality of care in better way where patient is allowed entering their personal data and it can be seen at the time of hospital visit and real time basis. Depending on the data, the report is generated and stored in secure manner. Cloud based patient health record (PHR) system by creating clinical document architecture (CDA) is analyzed in [2]. CDA is developed to make decision to cure major disease for a clinical support system and it is designed as a mobile application. In this paper, both PHR and EHR are integrated as per the medical standards such as HL7 and ICD-9-CM. Static CDA is developed to store permanent data such as personal information, contact detail, blood types, etc, and dynamic CDA is developed to store temporary data such as blood pressure and sugar level. Cloud based real time storage of health record for Indian healthcare needs is described in [4]. Clinical record of outdoor patient record is maintained for 5 years and indoor patients record is maintained for 10 years therefore EHR is used to maintain for once own life time. This paper mainly focusses on to ensure security and privacy into mobile network based on cloud management system. Healthcare data is encrypted and stored in a third party server.

Literature [6] addresses the practical implementation of EHR Server framework for Open EHR standard and its support in the clinical treatment of Chikungunya by the Brazilian Government and health service non-public providers. Electronic Patient Record (EPR) in the Health Information Systems (HIS) of a sanatorium is accessible whenever and wherever required by considering various measures like proprietary systems engineered with different design, business rules, info technologies and models, additionally to incompatible clinical language. [8] deals with smart healthcare monitoring system via internet of things to collect and to monitor health information. Authors designed this system to collect data of health via wearable devices through application programming interface (API) technology using open source front end web application development technologies such as Hyper Text Markup Language (HTML), JavaScript, back end hypertext preprocessor and MySQL database management systems. The health information is retrieved using application programming information (API) and it act as healthcare advice system. Monitoring the continuous patient's health care after discharge from hospital is briefed in the research article [10]. The internet based electronic medical record (EMR) is designed with assorted functions such as template function, log and medical record query function, record writing function, system configuration function and quality control function. A platform is developed to establish communication between patients and healthcare experts where information is stored in database and can be viewed whenever it requires for further treatment.

The information shared between doctor and patient is very sensitive there is in need of security to keep data very confidential and private. The essentials of maintaining confidentiality, privacy and security of patient's EHR are studied in [13]. A system is developed to allow doctors to upgrade data in database through their authentication credentials and to allow patients to see their data by private key through digital signature. In the paper [14], block chain-based Personal health record (PHR) system is developed with the system components like Ethereum, proxy re-encryption, trusty oracles, reputation systems, and Inter Planetary File System (IPFS). It allows patients to have a control over their medical records with certain authentication to maintain privacy and security access. The accuracy and correctness of maintaining PHR using Ethereum block chain –smart contracts is also validated. [15] addresses to demonstrate the use of simulation tool to balance the hospital resources to reduce waiting time of patients through interfacing graphical features for decision making.

PROPOSED METHODOLOGY

In this paper one umbrella approach is proposed to share the data pertaining to healthcare information services with various stakeholders of Healthcare industry such as doctors, nurses, patients, hospital management, authorities of clinical laboratory/diagnostic Centre, and pharmacy in a secured manner under one umbrella infrastructure[3,5]. Special care is taken to develop one umbrella approach by not altering the existing infrastructure of the healthcare services to save the huge installation and operational cost of the healthcare service providers.

One Umbrella Architecture

The existing information and communication facilities in the hospital to implement HIS are computer systems, network

switches/routers for wired communication and Wi-Fi access points for wireless communication. The stake holders may have digital tablets, smart phones which are connected with internet through gateway. These infrastructures can be utilized in an efficient way to form one-umbrella architecture to integrate the stake holders. The one umbrella architecture is illustrated in Fig. 1.

EHR is very essential in tracking and monitoring the patients health conditions continuously in order to make prior decision making in diagnostic process or therapeutic process. The requirements must be taken into account such as,

- 1) Smart Devices: Smart devices generally connected to another platform via wired and wireless protocols such as Ethernet and Wi-Fi.
- 2) Gateway: It is a networking hardware used for communication that allows the data to transfer. It allows connecting huge network for multiple access either through wired or wireless protocol.

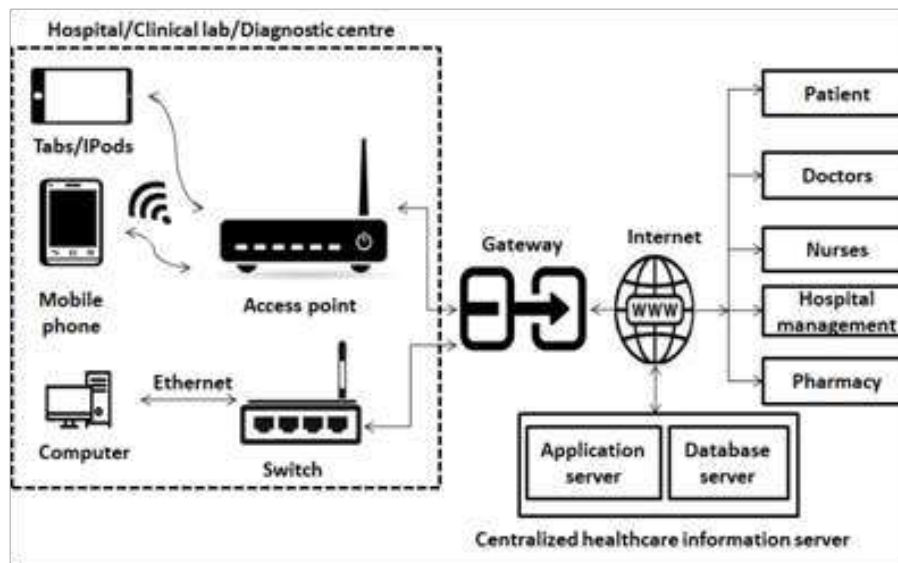

Fig. 1. One Umbrella Architecture

- 3) Server: Server, which provides data to other device and to serve data via local area network (LAN) through switches/access points and wide area network (WAN) over the internet via gateway.
 - Application Server: It is a server which consists of both hardware and software to run OUMS web application. It is served by the HTTP protocol with secured digital signatures and certificates. It compiles the application server side scripts and generate client machine understandable HTML format which can be viewed in web browser. Application Programming Interfaces (APIs) are installed in the server to transact the data with the relational database management system (RDBMS). The performance of the application server is ensured with various hardware configurations such as processor, random access memory (RAM), etc. Also server side scripts run on this application server should be optimized to reduce the processing time.[7,9].
 - Database Server: It is a server software which runs a RDBMS. This server is used to store, update and retrieve the patient’s information and health records in a secured manner.

Flow of Web Application

Web application is an open framework where the patient, physicians and other health care providers can communicate each other on real-time whenever necessary by simply registering. Based on patient medical report digital prescription is given to the patient depending on the health problems. The process of flow for the operation designed for web application is shown in Fig. 2.

HTML is a standard markup language which is used for the front end for developing web application. It is assisted by CSS and scripting languages such as Bootstrap and JavaScript to create attractive web pages. On other hand .NET web framework is used as back-end framework as a web application.

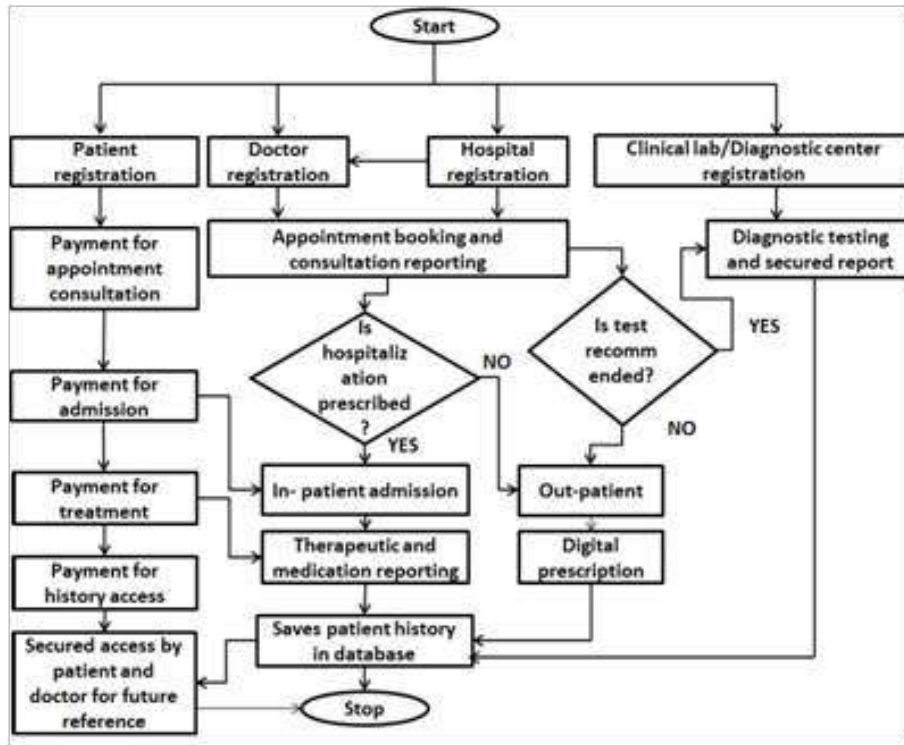

Fig. 2. Process flow for web application

Security and privacy

Advancement in technology security and privacy is most important in the EHR. The system can be accessed through a web portal by health care providers where it requires confidential information. So it can able to keep safe from unauthorized access. The security and privacy system is developed as shown in Fig. 3.

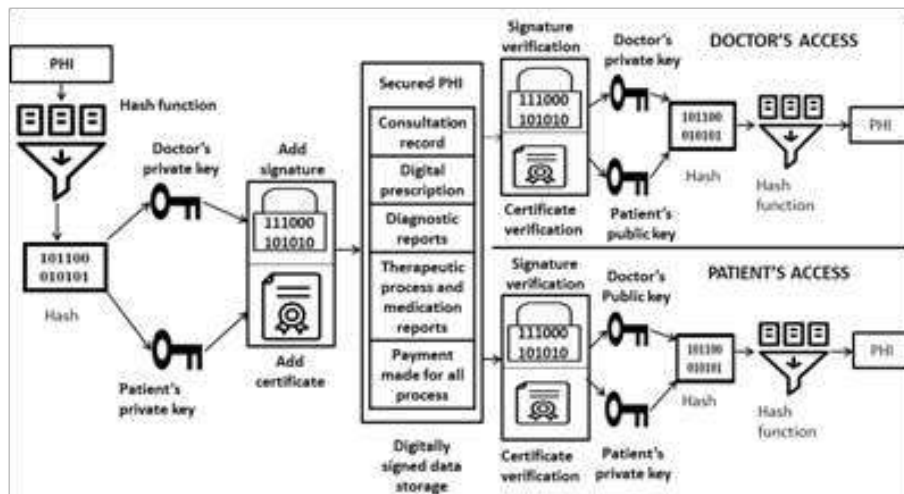

Fig. 3. Security and privacy structure

Security and privacy requirements must be taken into account such as,

- 1) PHI: Protected health information (PHI) is about any information regarding health conditions, the provision of health care status or payment regarding health care created by health institutions.[12]

2) Sign In

- Hash Function: It is one of the methods to encrypt the data. The arbitrary size of data is mapped in the form of the bit array in order to require fixed size.
 - Private Key: Both encrypted and decrypted data is allowed to share between patient's and health care providers of encrypted data.
 - Add Signature and Certificate: Signature act as secure lock and it requires a certificate. Both are compared to provide a digitally signed data.
- 3) Data Storage: Information regarding the patient's health status is stored in digitally signed data for secure manner. It consists of consultation record, digital prescription, the therapeutic process and medication reports, diagnostic report and payment made for all process.
- 4) Verification: Doctor's and patient's can access once digitally secured data by following the process as,
- Doctor's Access: A Public key is accessed by the patients and private key by doctors which is shared between two parties only are compared. Where encrypted data is converted into its original form known as decryption. If decrypt and encrypt are equal authorized person can access.
 - Patient's Access: A Public key is accessed by doctors and private key by the patients which is shared between two parties only are compared. Where encrypted data is converted into its original form known as decryption. If decrypt and encrypt are equal authorized person can access.

EXPERIMENTATION

The front end web application designing languages such as HTML, bootstrap styles, cascaded style sheets and java scripts are used to design graphical user interface for doctors and patients. ASP.net technology is used as the back end programming language to do data access control in the application server. MySQL RDBMS is used to store and retrieve the encrypted data .

Base64 is a MIME encoding scheme that encode binary to text, which represents binary data in an ASCII strong format. Translation is done through radix 64 for hashing the PHI.

Data encryption and secured storage algorithm for OUMS

- Step (1) : First layer encryption is done on the patient health information using base 64 based hashing function
- Step (2) : Second layer encryption is done using doctor's private key and patients private key to offer strong protection against data attacks.
- Step (3) : Include digital signature and digital certificate for storing PHI in the secured data storage system.

Data decryption and secured accession algorithm for OUMS

- Step (1) : Verify the digital signature and digital certificate for accessing the secured data storage in OUMS
- Step (2) : Second layer decryption is done using doctor's private key and patients public key to read the base 64 encrypted hashed PHI if it is read by a doctor.
If the decryption is done by a patient, the doctor's public key and patients private key are used to decrypt and read base 64 hashed PHI
- Step (3) : First level decryption is done using base 64 to binary data in order to recognize PHI for decision making in medication process.

QR code based encoding and decoding procedure is used in the second layer encryption and decryption process to understand the public key of the patient during the doctor's access and the public key of the doctor using the patient's PHI data access.

RESULTS AND DISCUSSIONS

Table 1 shows the original PHI of a patient during the hematology test and the corresponding hashed value given to the second level encryption using private keys.

Table 1. Base 64 encrypted hash table for first level encryption

S. No.	PHI			hashed PHI
	Hematology Parameters	Observed Value	Units	Encoded HASH value
1	Hemoglobin	175	g/L	MTc1
2	Platelet count	350	10 ⁹ /L	MzUw

Fig 6. Screen shot for reading doctor's public key

CONCLUSION

The proposed one umbrella system has been established, implemented, and tested with private and public keys in a secured manner. In this paper, both patient and doctor could be able to send their data using their public and private keys. It is ascertained that unknown persons were not allowed to enter and view or manipulate the medical records of the intended user and thereby high confidentiality is maintained in the healthcare management services. Further the research will be extended to have HIS for healthcare imaging modalities also.

ABSTRACT

Miniscule payloads are minute secret information in the form of binary bits hidden inside any cover image for the purpose of undercover communication by steganography. Steganography when misused by unlawful entities can pose a great threat to law enforcement agencies. Detection of such low volume payloads from a stego image is the very challenging task of steganalysis when there is no evidence of steganography method or any steganography tool used. Location of minuscule payloads is possible through sophisticated cover estimators and need not be necessarily in their logical order. In this paper an extraction technique is proposed, in which multiresolution transform based cover estimation is combined with weighted residual based location estimation to recover low volume payloads from stego images created with Least Significant Bit (LSB) steganographic schemes such as LSB-Replacement (LSBR), LSB-Matching (LSBM), LSBM-Revisited (LSBMR) and 2 bit LSBR (LSBR2). Among the various multiresolution transforms analysed, such as discrete wavelet, dual tree complex wavelet, ridgelet, curvelet, contourlet, shearlet, wavelet packet, and tetrolet, the dual tree complex wavelet transform is identified as the best transform to produce an accurate cover estimate of stego image and results in 85 % accuracy in locating payloads from stego image. Experimental results show that in order to locate payloads, lesser number of stego images containing payload in same locations are needed while using DTCWT for cover estimation.

Keywords : Image steganalysis; Wavelet Transform; Bivariate Shrinkage; Residual Extraction; Least Significant Bit Steganography; Payload Location.

INTRODUCTION

In digital image steganography, a cover image is used to hide a secret (or payload) through the use of embedding techniques namely Least Significant Bit (LSB) schemes, group-parity steganography, and matrix embedding to get a stego image. While embedding the payload, pixels in the cover image are modified in such a way that the modifications are imperceptible to a human eye. The job of a steganalyst becomes very difficult in a blind environment i.e., only suspicious stego images are at hand and no knowledge regarding the source of cover or size or location of payload. In such conditions, steganalysts assume a clairvoyant scenario [1]. Provided that the naive steganographer reuses the embedding key in order to locate payload in same pixel location and a large number of such stego images are available for a steganalyst, location of payload can be detected reliably without the knowledge of the original cover source. To achieve this goal, several steganalytic methods are developed to extract the hidden information.

The work was sponsored by Directorate of Extramural Research & Intellectual Property Rights (ER & IPR), Defence Research Development Organization (DRDO), Ministry of Defence, Government of India under Grant No. ERIP/ER/201702007/M/01/1733.

The first approach [2] is the identification of location of payloads with determined stego keys by brute force method (dictionary attack) with a trace from the image header. Fridrich et al. [3] proposed a chi-square based method to find the stego key by an exhaustive search of the de-noised image beside portions of the embedding path. When textured or noisy images having a large key space is used as cover, their method was not successful. Also, it required the embedding scheme to be known in advance.

The work was sponsored by Directorate of Extramural Research & Intellectual Property Rights (ER & IPR), Defence Research Development Organization (DRDO), Ministry of Defence, Government of India under Grant No. ERIP/ER/201702007/M/01/1733.

Ker [4] deployed a novel method of using weighted stego filters to determine the locations of payload for LSBR steganographic algorithm. This method requires large number of stego images (say 500 images) embedded with same stego key. Later, Ker and Lubenko [5] redeveloped the weighted averages residuals using Wavelet Absolute Moments (WAM) in the spatial domain to estimate locations of payloads for LSBM algorithm. For their work, several databases created using different camera sources were used for validation purposes. Luo et al. [6] proposed the residual method of identifying location of payload for LSBM with 2 and weighted l2 residuals. Though, only the sections of images and smaller images were considered in order to locate the payloads in low volume (1%). Then, Quach [7] developed a new method of estimating payload location using cover estimation techniques by Maximum likelihood A Priori (MAP) decoding and second-order statistical cover model to compute residuals for both LSBR and LSBM algorithms. Later, Quach [8] improved his work by tree pruning method to obtain an accuracy of 99.39% for LSBR and 92.34% for LSBM with 1000 images. Gui et al. [9] suggested a trivial modification to the earlier work, where estimation of cover was done in eight different directions instead of one for LSBM algorithm. Quach [10] proposed Markov Random Field (MRF) and MRF+MAP methods to estimate locations with fewer images and with higher precision for simple LSB and group parity steganographic schemes. But, all these methods required the knowledge of the cover source and needed a few thousand cover images to train the steganalyser to find the prior probabilities for cover estimation. Veena et al. [11] proposed an improved method of identifying location of payload using enhanced weighted residuals extracted from the stego and its estimated cover. The cover image is estimated from the stego image by a locally weighted bivariate shrinkage function in transform domain (Discrete Wavelet Transform (DWT) and Dual Tree Complex Wavelet Transform (DTCWT)). This method required only prior knowledge of relative payload size and only a few hundred stego images embedded with the same stego key. This method was extended to five spatial LSB variant schemes for five different payloads.

The success of payload location depends on the accuracy of the cover estimators. Various methods are used to estimate cover from the stego in a blind steganalysis process, the predominant being spatial domain filtering, wavelet filtering, Markov modeling and locally weighted bivariate shrinkage function using Wavelet transforms (DWT and DTCWT). The enhanced weighted residuals ensure that the transform domain method is universally applicable for detecting payload locations in spatial least significant bit stego images. The added advantage of this method is that it does not require any prior knowledge of the cover source or the embedding algorithm to determine the exact locations.

In this paper, performance of various cover estimators with multiresolution transforms such as discrete wavelet, dual tree complex wavelet, ridgelet, curvelet, contourlet, shearlet, wavelet packet, and tetrolet are analysed. From the estimated covers, payload location estimation is carried out using weighted residual extraction process.

The rest of the paper is organized as follows: Section 2 explains the proposed methodology; Section 3 provides the experimental setting and Section 4 presents the results and discussions. Section 5 concludes the research work with future scope.

PROPOSED METHODOLOGY FOR COVER ESTIMATION AND PAYLOAD LOCATION

The proposed block diagram for cover estimation and payload location is depicted in **Fig. 1**. The first step in the proposed method is to estimate cover image from a given stego image.

Fig. 1. Block Diagram of the Proposed Method

This process is similar to image denoising since steganography is purposefully adding a stego noise to an innocent cover. Image denoising is performed using multiresolution transforms to obtain a cover estimate. Under the Clairvoyant scenario, several stego images with same embedding key to hide payloads at same location are taken and their cover estimates are obtained. After the estimation of cover images, weighted residuals are calculated from stego and estimated cover images. From the weighted average residuals, locations of payload are identified that correspond to the estimated secret message length. Making use of a priori information i.e., stego key, from the extracted locations' pixels the least significant bits are retrieved and the hidden payload is obtained.

Cover Estimation by Image denoising Technique using Multiresolution Transforms

The estimation of cover from stego images is vital in order to extract payload locations. The process of cover estimation using locally weighted bivariate shrinkage function is depicted using a flow chart in **Fig 2**. Cover estimation can be considered as image denoising process since hidden payload is characterised as additive noise.

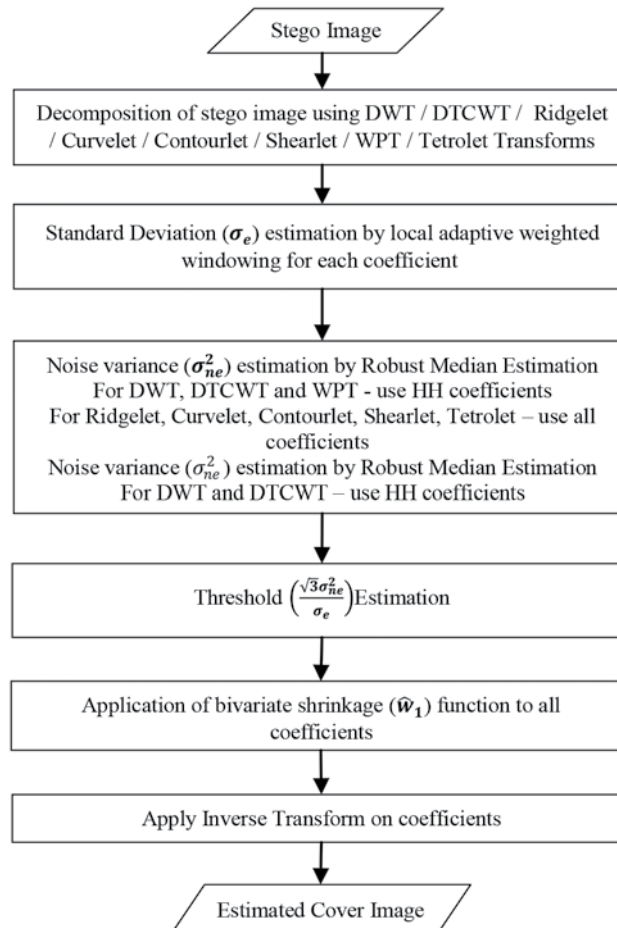

Fig. 2. Flow chart for Cover Estimation in the Proposed Method

In this paper, the stego images are subjected to different wavelet transforms (Discrete Wavelet Transform (DWT), Dual Tree Complex Wavelet Transform (DTCWT), Ridgelet, Curvelet, Contourlet, Shearlet, Wavelet Packet Transform (WPT) or Tetrolet) and the image pixels in spatial domain are converted into transform domain coefficients. DWT [12] is implemented as a set of high-pass and low-pass filter banks. At the cost of approximate shift-invariance, Kingsbury introduced the DTCWT [13], which has the added characteristic of Perfect Reconstruction and implemented as two separate two-channel filter banks. Ridgelet transform [14] effectively maps line singularity to point singularity using Radon transform. Curvelet transform [15], one of the multiscale geometric transforms, attempts to overcome the inherent limitations of traditional multistage representations such as wavelets and provides the options to analyze an image with different block sizes, by using with a single transform. Contourlet transform [16] is a directional transform which is capable of capturing contour and fine details in an image. Shearlet [17] decomposition procedure is initiated by separating the image into its high pass and low pass components, which is accomplished using Laplacian pyramid. WPT [18] applies the DWT decomposition to both the low pass and the high pass resultants. Tetrolet Transform [19] is a geometric adaptive transform having tetromino support and the potential to adapt to the directional features of an image. In [11], the authors have relied on DTCWT for cover estimation, whereas in this work an extension of [11] is carried out by studying the performance of seven other transforms and the best cover estimator is identified. Then, a locally weighted bivariate shrinkage function is applied on these coefficients. Then appropriate inverse transform is

applied on the denoised coefficients which results in the estimated cover image pixels. According to Zong [22], there exist strong dependencies between neighbour coefficients such as between a coefficient, its parent (adjacent coarser scale locations) and siblings (adjacent spatial locations) in transform domain. In the basis of an orthogonal wavelet transform, a stego image S in transform domain can be represented using equation (1).

$$y_k = w_k + n_k \tag{1}$$

where, y and w are the k^{th} wavelet coefficients of the stego (S) and cover (C) images respectively. Let w_{2k} represent the parent of w_{1k} . w_{2k} is the wavelet coefficient at the same position as the k^{th} wavelet coefficient w_{1k} , but at the next coarser scale. Let y_{1k} and y_{2k} be noisy observations of w_{1k} and w_{2k} and n_{1k} and n_{2k} are noise samples. It is formulated as $y_{1k} = w_{1k} + n_{1k}$ and $y_{2k} = w_{2k} + n_{2k}$ to take into account the statistical dependencies between a coefficient and its parent. Hence, $w_k = (w_{1k}, w_{2k})$, $y_k = (y_{1k}, y_{2k})$ and $n_k = (n_{1k}, n_{2k})$. The joint shrinkage function[23] is given by equation (2).

$$w = \frac{\left(\frac{\sqrt{y_1^2 + y_2^2} - \sqrt{3}\sigma_{ne}}{\sigma_e} \right)_+}{\sqrt{y_1^2 + y_2^2}} \cdot y_1 \tag{2}$$

where, g_+ is soft thresholding. This function is used for wavelet transforms like DWT, DTCWT and WPT. This estimator requires the prior knowledge of the noise variance σ_{ne}^2 and the marginal variance σ_e for each wavelet coefficient. σ_{ne}^2 estimated by robust median estimator given by equation (3).

$$\sigma_{ne}^2 = \frac{\text{median}(|y_i|)}{0.6745}, y_i \in \text{subband HH} \tag{3}$$

The marginal variance for the k^{th} coefficient will be estimated using neighboring coefficients proposed by Sendur et al. [24] in the region $N(k)$. From the observation model, $\sigma_y^2 = \sigma_e^2 + \sigma_{ne}^2$ where σ_y^2 is the marginal variance of noisy observations y_1 and y_2 .

An average filter is used to locally estimate the signal's standard deviation. A weighted local window mentioned in [11], $f = \frac{1}{13} \begin{bmatrix} 1 & 3 & 1 \\ 3 & 6 & 3 \\ 1 & 3 & 1 \end{bmatrix}$ is used for estimating the standard deviation, σ_e . This weighted filter is especially useful for LSB steganography where the minute changes of embedding have to be removed while preserving the other information details. Since y_1 and y_2 are modeled as zero mean, σ_y^2 can be found empirically by equation (4).

$$\sigma_y^2 = \frac{1}{M} \sum_{y_i \in N(k)} f \times y_i^2 \tag{4}$$

where, M is the size of the neighborhood $N(k)$. Then, σ_e can be estimated by equation (5),

$$\sigma_e = \sqrt{\left(\sigma_y^2 - \sigma_{ne}^2 \right)_+} \tag{5}$$

After calculating σ_e and σ_{ne}^2 , using equation (5) each coefficient is estimated. Unlike DWT, DTCWT and WPT, the Ridgelet, Curvelet, Contourlet, Shearlet, Tetrolet and QWT transforms do not have parent and siblings relationship. So, the computation of the joint shrinkage function [25] is given by equation (6).

$$w = \frac{\left(\frac{y - \sqrt{3}\sigma_{ne}}{\sigma_e} \right)_+}{y} \cdot y_i \tag{6}$$

where, y represents coefficients of Ridgelet, Curvelet, Contourlet, Shearlet, Tetrolet and QWT transform decomposition. The calculation of noise variance and signal standard deviation are same as equations (3-5). The output of the above filtering excavates high residual values at the embedding points, while preserving the nature of the image at other locations. Thus, the locally weighted bivariate shrinkage using DWT and DTCWT coefficients are perfectly reconstructable and provide the estimated cover in spatial domain (\hat{C} □).

Location Estimation by Weighted Residual Extraction

After the estimation of cover images, weighted residuals are calculated from stego and estimated cover images. From the

weighted average residuals, locations of payload are identified and the count of these locations correspond to the estimated secret message length. In the residual extraction, the first step is to find the difference between the stego image and its estimated cover image. In general, the residual (r_k) is obtained by equation (7).

$$r_k = |S_k - \hat{C}_k| \tag{7}$$

where S_k and \hat{C}_k are the k^{th} stego and estimated cover images respectively. However, using weighted residual boosts varying levels of confidence in the predictor by a weight, which is local variance dependent. In a local 3×3 window of the residual matrix centered at (i, j) , a weight $w_{i,j} = \frac{1}{5000 + \sigma_{i,j}^2}$ is applied. Since the residuals are minuscule for a single image, it is customary to accumulate residuals of a few hundred to thousand images to identify the locations precisely and hence, the weighted mean residual \bar{r} obtained over N images is given by equation (8).

$$\bar{r} = \frac{\sum_{k=1}^N r_k \times w_k}{N \times \sum_{k=1}^N w_k} \tag{8}$$

The residual is taken as such and a prior knowledge of relative payload (M) is obtained from a quantitative steganalyzer [11]. The highest M non-zero magnitude residual coordinates are identified as the spatial locations. This method uses only the relative payload (M) information to find the locations for all algorithms with no other prior information of cover.

EXPERIMENTAL SETTING

The evaluation of the proposed work is carried out on the stego images created using Least Significant Bit algorithms and their variations. The Least Significant Bit (LSB) variant algorithms are non-content adaptive i.e., the payloads are hidden in a random fashion throughout the image without considering image contents like edges and textures. The algorithms considered are LSB-Replacement (LSBR), LSB-Matching (LSBM), LSBM-Revisited (LSBMR) and 2 bit LSBR (LSBR2). In LSBR, the LSB of a cover image is replaced by random secret bit to produce the stego image, whereas in LSBR2, the last two LSBs are altered with random secret data. The main principle of LSB embedding is the inherent asymmetry with even values either unchanged or increased by 1 and odd values either unchanged or decreased by 1. With this idea, LSBM [20] (also known as ± 1 embedding) embeds the secret bit randomly by either by adding or subtracting from cover image, if the secret data bit does not match the LSB of cover image. In LSBMR [21], the embedding of random secret data is achieved using a pair of pixels as a unit so that lesser pixel change rate is achieved than LSBM. The cover database for generating stego images is taken from Bossbase v1.01 which consists of 10,000 grayscale images of size 512×512 . Stego images are generated with six different very low volume relative payloads such as 0.01 bpp, 0.02 bpp, 0.03 bpp, 0.04 bpp, 0.05 bpp and 0.1 bpp using the four LSB algorithms. The embedding is done in such a way that the bit change rate remains the same. So, for a fixed payload of 0.1 bpp, 0.05 bpp, 0.04 bpp, 0.03 bpp, 0.02 bpp and 0.01 bpp, the single-bit schemes such as LSBR, LSBM, LSBMR embed in 26214, 13105, 10484, 7863, 5243 and 2621 pixels respectively, 2 bit LSBR (LSBR2) being multibit scheme embed in 13107, 6554, 5423, 3932, 2621 and 1311 pixels respectively using the same stego key. However, the payload is random and no two images have the same payload embedded in them. For this purpose, random N images are chosen and residuals are computed, where N assumes values of 1, 10, 100, 500 and 1,000.

EXPERIMENTAL RESULTS AND DISCUSSIONS

The accuracy of correctly identified pixels for different LSB stego images using DWT, DTCWT, Ridgelet, Curvelet, Contourlet, Shearlet, WPT and Tetrolet transforms is presented in this section. The accuracies for Payload Location Estimation in LSBR and LSBM stego images using Different Transforms for different N values such as 1, 100 and 1,000 are provided in a graphical format in Fig. 3.

From Fig. 3, it can be observed that, the proposed method of payload location by using cover estimation with DTCWT reigns supreme in all experiments. When the number of stego images considered to locate payloads is increased, the detection accuracy is also increased and vice versa. In the case of stego images created using LSBR algorithm, by using DTCWT cover estimation, even for a single known stego image ($N = 1$), the identification of pixel location is high in very low volume payload (0.01 bpp) i.e., 774 pixels are located and for 0.1 bpp payload, 9461 pixels are located with an accuracy of 29.53 % and 36.09 %

respectively. Using DTCWT, it is also inferred that for $N = 1000$, the accuracy is about 99.95 % and 97.9 % for 0.1 bpp and 0.01 bpp respectively. DTCWT is able to provide a better result due to its directional selectivity and shift invariance property. On comparing DWT, Ridgelet, Curvelet, Contourlet, Shearlet, WPT, Tetrolet and QWT transforms, Contourlet performance is better due to its Laplacian pyramid transformation along with directional filter banks.

From Fig. 3, it can also be observed that, for LSBM, by using DTCWT cover estimation, for a single known stego image the accuracy of locating payload is about 11.5 % for 0.1 bpp and 1.53 % for 0.01 bpp. But, when N is increased, the accuracy is also increased to 97.89 % (25661 pixels) and 97.25 % (2549 pixels) for 0.1 bpp and 0.01 bpp respectively. In case of Contourlet transform, for 0.1 bpp when $N = 1000$, 97.25% (25492 pixels) accuracy is achieved and for 0.01 bpp, 92.4 % (2428 pixels) accuracy is achieved. There is only 0.64 % accuracy increase between DTCWT and Contourlet transforms for $N = 1000$ (0.1 bpp). This is because of embedding pattern of LSBM algorithm. In case of DWT and Curvelet transforms, DWT performs better and its accuracy of identifying of locations of payload (0.1 bpp and 0.01 bpp) when $N = 1000$ is 88.16 % (23109 pixels) and 76.34 % (2001 pixels).

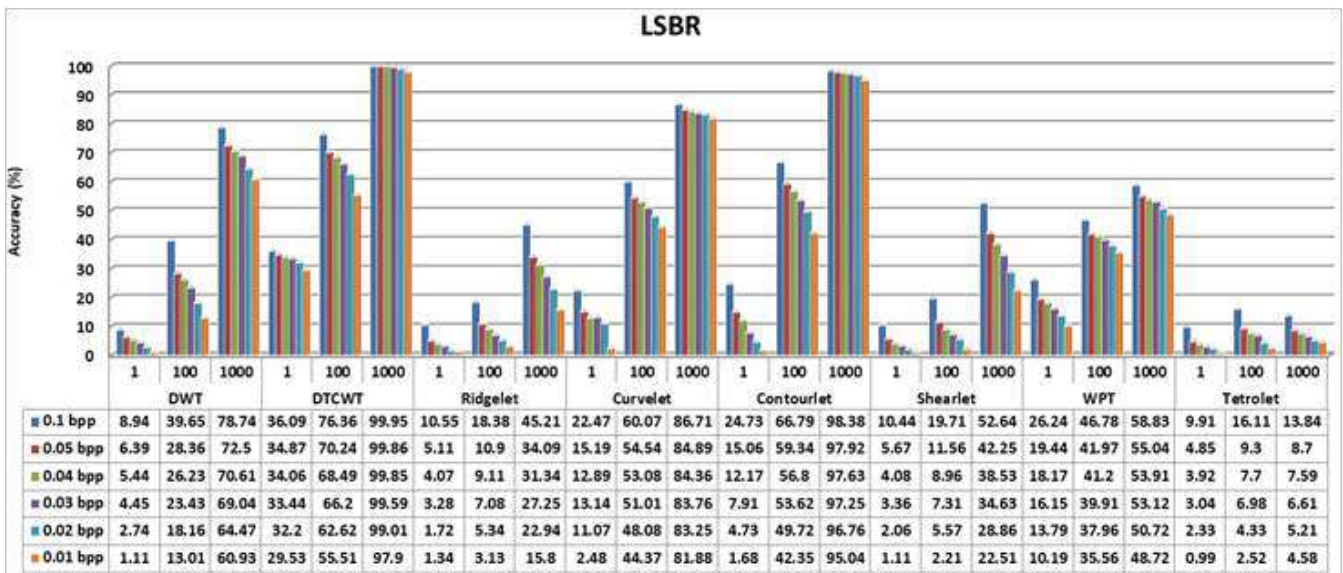

The accuracies for Payload Location Estimation in LSBR and LSBM stego images using Different Transforms for different N values such as 1, 100 and 1,000 are provided in a graphical format in Fig. 4.

From Fig. 4 it can be inferred that, DTCWT performs better than other transforms. In the case of LSBMR algorithm, For $N = 1$, the accuracy of locating payload is 14.2 % (3781 pixels) for 0.1 bpp and 1.79 % (47 pixels) for 0.01 bpp. When $N = 1000$, the accuracy is increased to 87.08 % (22826 pixels) and 78.9 % (2068) for 0.1 bpp and 0.01 bpp respectively. In the case of LSBR2 algorithm, for $N=1$, accuracy of correctly identified pixels for very low volume payload of 0.01 bpp is 33.64 % and 36.74 % for 0.1 bpp. As N increases (200 to 500), the accuracy also increases to about 97 % for 0.1 bpp and when $N = 1000$, the accuracy is of 99.2 % (13002 pixels) which is only 105 pixels less to the total number of pixels (13107) embedded.

From Fig. 4, it can be concluded that the proposed method using DTCWT and Contourlet perform better in the identification of the location of payloads in all LSB algorithms for varying payloads (0.01 bpp, 0.02 bpp, 0.03 bpp, 0.04 bpp, 0.05 bpp and 0.1 bpp) with high accuracy.

Fig. 5 provides a comparison for payload location estimation accuracy using DTCWT for all the algorithms. From Fig. 5, it is observed that the correctly identified payload pixels are less in LSBMR algorithm than the other algorithms. This is due to the embedding pattern of LSBMR algorithm which makes the steganalysis task difficult.

Table 1 - 4 provides the extracted payload from these locations when considering stego images from all the LSBR algorithms.

From **Table 1-4** it is clearly seen that, when N is increased, the payload can be extracted with minimum errors across all payload bins. The quality of the reproduced secret is of the order LSBR2, LSBR, LSBM and LSBMR. The reason is that LSBR2 has double embedding pattern, LSBR and LSBM becomes nearly the same with same key embedding and LSBMR is difficult than these because of its embedding change rate and pattern. It is evident that, more the availability of stego images that too in a clairvoyant scenario the embedded secret can be extracted. At least a 100 stego images are required to have a clue of the embedded secret, but in case of LSBR2, the embedded secret begins to be visible with only 10 stego images since the embedding bit is twice compared to other algorithms.

CONCLUSION

In this paper, comparative analysis of various multiresolution transforms in cover estimation of stego images for payload location estimation is thoroughly studied. From the experimentation done, DTCWT is chosen to be the best cover estimator. In addition to DTCWT, Curvelet and Contourlet based cover estimation also detects the locations with better accuracy because of their efficiency to decompose the stego images while preserving the edges and contours. DTCWT performs better than DWT since it accounts for the positive and negative frequencies and hence it results in providing increased level of directional sensitivity and perfect reconstruction of stego images. Based on the experimentation, the order of transforms that are able to locate the payload with high accuracy is found to be DTCWT, Contourlet, DWT, Curvelet, WPT, Shearlet, Ridgelet and Tetrolet for all algorithms. It is observed that, payload location in LSBMR stego images is somewhat difficult compared to other LSB algorithms since in LSBMR, pixel change rate is very less. Under the Clairvoyant scenario, secret is also extracted from the stego images of all the four LSB algorithms.

Since, in this proposed method a greater number of stego images embedded using same stego key are needed to get a high accuracy for payload location, the work can be extended in future with a minimum number of stego images.

ACKNOWLEDGMENT

The authors would like to thank ER & IPR - DRDO New Delhi, Management and Principal of MepcoSchlenk Engineering College, Sivakasi for providing the necessary facilities and support to carry out this research work.

ABSTRACT

Manufacturing has been an essential component of the Indian economy which fosters self-reliance. One of the top manufacturing industries in India in the present scenario is the concrete industry whose core ingredient is cement. Potential problems associated with the concrete industry include the generation of carbon dioxide due to the production of cement that in turn, leads to exhaustion of limestone reserves. Therefore, it is critical to find sustainable manufacturing methods for the production of concrete and move towards sustainable development. In this paper, the authors stress the importance of adopting geopolymer concrete as an alternative to traditional cement. From the available literature, the compressive strength properties of various industrial waste-derived geopolymer concrete have been highlighted and tabulated. Besides, the paper also explores the implications of using geopolymer concrete on the environment, thus promoting its use, as an effective method of sustainable concrete manufacturing.

Keywords : Geopolymer concrete; Sustainable development; Cement production; Sustainable manufacturing.

INTRODUCTION

Sustainable manufacturing refers to the type of manufacturing which improves the environmental performances of the end products while reducing production costs, waste generation, consumption of natural resources, and carbon emissions as well. The chief driving force of the economy is the manufacturing sector which also has the ability to shape the society into a more sustainable one. The last decade witnessed a rapid growth in the infrastructure sector in India and the demand for concrete has increased manifold. However, the traditional concrete that is widely used for infrastructure development requires cement for its production and thus responsible for 7-8% of the total greenhouse gas emissions (CO₂) and global warming [1]. Further, the manufacturing of cement consumes natural reserves of limestone and is an energy-intensive process that requires high thermal energy for calcination of limestone and combustion of fossil fuels for clinker production. Apart from this, there is generation of solid wastes such as kiln dust and other solid particulates. To address this growing concern of unsustainability in the concrete manufacturing sector, it is high time to escalate the pursuit of alternative binders and concrete and out of these alternatives, geopolymer concrete seems to an ideal choice from the perspective of sustainable development.

Geopolymer concrete is a cement-less construction material which is produced from alkali activation of industrial aluminosilicate solid wastes, for instance - fly ash (FA), ground granulated blast furnace slag (GGBFS), rice husk ash (RHA), Palm oil fuel ash (POFA), silica fume (SF), ferrochrome slag (FS) and ferrochrome ash (FCA) etc. The alkali activators are usually a mixture of sodium hydroxides and silicates. The manufacturing of geopolymer concrete is considered to be more sustainable than traditional cement-based concrete as there is less energy requirement and carbon emissions are reduced by 70-80% - in the absence of cement. Moreover, it provides a pathway for the implementation of circular economy in the construction sector i.e. conversion of wastes to wealth. It can be prefabricated easily and the literature suggests that the strength and durability properties are outstanding when compared to the cement-based concrete [2,3].

The primary motivation for this study includes the overview of the compressive strength properties of various types of geopolymer concrete made out of different industrial wastes in the last decade. This paper also strives to promote green and sustainable manufacturing of concrete, thus serving to reduce environmental impacts caused due to the traditional method of manufacturing concrete.

PREPARATION OF GEOPOLYMER CONCRETE

Although the preparation of geopolymer concrete is similar to the preparation of cement-based concrete, there is a slight difference in the type of ingredients used. The ingredients of geopolymer concrete essentially include the source materials

(aluminosilicate industrial wastes), alkaline solutions, and conventional aggregates – presented in **Fig. 1**. The chemical composition of source materials plays a significant role in the strength development of the geopolymer concrete samples. Higher the Si/Al ratio of the source materials, the greater is the rate of geopolymerization i.e. stronger covalently bonded -Si-O-Al- framework. The alkaline solutions are generally taken as a mixture of solutions of sodium hydroxide and silicate at a fixed mass/volume ratio. Interestingly, the geopolymer concrete does not necessarily require any additional water during the mixing process, instead, water is expelled during the reaction process, which is very helpful in maintaining the fluidity of the mixtures. Moreover, the need for water curing is also eliminated due to the absence of cement. However, the temperature is the principal governor of strength development over the ages. Researchers have therefore adopted the method of ambient curing [4] for in-situ casting purposes and the elevated temperature curing [5] for prefabrication requirements. Currently, ambient cured geopolymer concrete is more preferred, to enable its wide acceptance and implementations.

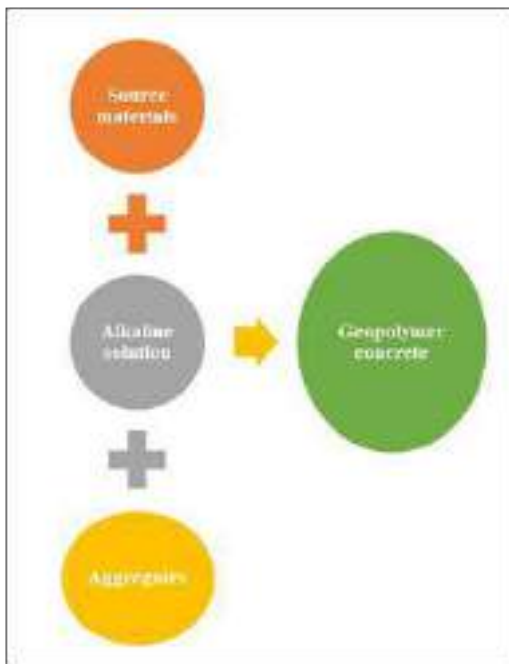

Fig. 1. Manufacturing of geopolymer concrete

COMPRESSIVE STRENGTH PROPERTIES OF VARIOUS INDUSTRIAL WASTE-DERIVED GEOPOLYMER CONCRETE

The compressive strength is considered to be the most vital mechanical property of any given concrete. In the case of cement-based concrete, the strength development is due to the generation of calcium silicate hydrate (C-S-H) gel whereas the formation of calcium aluminate silicate hydrate (C-A-S-H) and sodium aluminate silicate hydrate (N-A-S-H) gels are responsible for strength development in geopolymer concrete [6]. Since geopolymerization is a set of rapid and complex reaction mechanisms, the chemical composition of the source materials, therefore, is a crucial parameter to focus upon. For this reason, different source material composition exhibits a unique set of mechanical and durability properties. Besides, the compressive strength also depends on the concentration of sodium hydroxide, the ratio of sodium hydroxide and silicate solution (by weight or volume), temperature conditions among other factors – which are beyond the scope of this paper. Therefore, based on past literature (2010-2020), the present study highlights some of the source material compositions and their corresponding compressive strength results achieved under different curing regimes; presented in **Table 1**.

Table 1. Compressive strength properties of different source material combinations based geopolymer concrete

FERROCHROME ASH BASED GEOPOLYMER CONCRETE

The authors of this study recently prepared geopolymer concrete by blending FCA and GGBFS as source material combination, cured under outdoor conditions [17]. FCA is a waste obtained from ferroalloy industries while GGBFS is a by-product of the steel industry; their disposal is a great concern. The compressive strength achieved after 28 days of curing was found to be 32.6 MPa (as shown in Fig. 2) that could be used for general construction purposes. As a result, it serves as a potential alternative to cement-based concrete. The study also discussed the microstructure – scanning electron microscopy (SEM), fourier transform infrared spectroscopy (FTIR) analysis, of the resulted FCA based geopolymer concrete samples. Further, the authors highlighted the importance of the circular economy and elucidated its basic features.

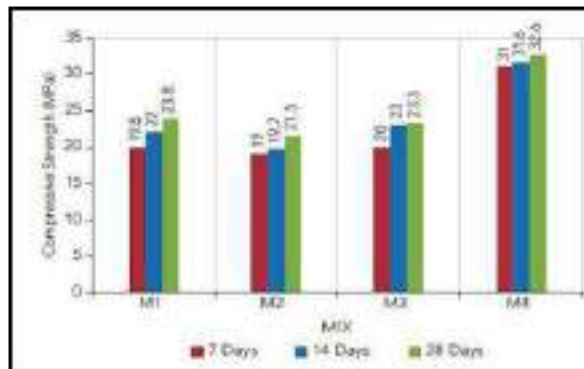

Fig. 2. Compressive strength of FCA based geopolymer concrete with GGBFS [17]

IMPLICATIONS OF SUSTAINABLE MANUFACTURING OF GEOPOLYMER CONCRETE

The geopolymer concrete is relatively a new construction material being adopted worldwide. Its conceptualization began in the 1970s by the French scientist, J. Davidovits who termed this as “geopolymer technology”. However, the durability and serviceability data require time, and almost after five decades of research, the data suggests that geopolymer concrete shows outstanding potential in comparison to the traditional cement-based concrete. In many parts of the world, especially in U.K and U.S.A, the geopolymer concrete has been rapidly adopted to address the concerns of the environment such as global warming, water shortages, exhaustion of natural reserves, and industrial waste disposals. Implementation of this green manufacturing in India may be considered to be the first step towards a sustainable future.

In the meantime, India faces challenges such as global warming, climate change, and acute water shortages. As discussed earlier, the issue of greenhouse gas emissions can be effectively addressed by the implementation of cement-less geopolymer concrete. Simultaneously, it is also observed that there are considerable changes in the timing of wet and dry seasons with a disturbed hydrological cycle. In 2019, India witnessed major rainfall accompanied with floods in its northern part which is contrary to the issue of acute water shortage in the southern part at the same time. Chennai became the first city to face an acute water shortage. The National Institution for Transforming India (NITI Aayog) report clearly states that India has been suffering from a significant water crisis for which economic growth, livelihoods, human well-being as well as ecological sustainability is at stake, and 21 major cities including New Delhi will run out of groundwater by 2020 [18]. These issues cannot be solved unless there is a focus on sustainable development and manufacturing. As the infrastructure demand rises in India, the demand for concrete will rise simultaneously. The traditional method of concrete manufacturing requires a huge amount of water for mixing and curing purposes, hence, sustainable manufacturing of geopolymer concrete, which essentially does not require any water, seems to be a prudent decision. This could save our natural water reserves from depletion and recover the groundwater table.

Another major advantage of adopting geopolymer concrete is that it helps mass utilization of industrial solid wastes and could lead to a circular economy. This model of economy may involve the construction sector and the concrete manufacturing sector to convert the wastes into the economy. The industrial wastes such as FA, GGBFS, RHA, FS, FCA are viable candidates for geopolymerization as they contain a significant amount of aluminum oxides and/or silicon dioxides. Presently, there has been some progress in the utilization of these wastes as pozzolanic materials for the production of blended cement-based concrete manufacturing in the construction sector. However, the full utilization of these wastes in the construction sector seems to be a challenge. Therefore, the implementation of geopolymer concrete could certainly enhance the utilization rate of these wastes and provide an alternative pathway for sustainable manufacturing thereby enabling the circular economy into the current scenario.

CONCLUSIONS

The carbon-conscious market drives the demand for the development of alternative sustainable ways of manufacturing. The research carried out so far has successfully established geopolymer concrete as an alternative to cement-based concrete. This paper elucidated the importance of sustainable manufacturing of geopolymer concrete. The traditional method of manufacturing concrete has become unsustainable, therefore it is high time to focus on the commercialization of geopolymer concrete, to build a smart and sustainable future. The core challenge, however, is the mutual participation of industry stakeholders, research agencies, and government policymakers.

A Geotechnical Study on Properties and Uses of Shales of the Dharwar System, Karnataka, India

Dr Udayashankar D Hakari

Associate Professor, Department of Civil Engineering, S.D.M. College of Engineering and Technology, An Autonomous Institute under Visveswaraya Technological University, Dharwad, Karnataka

*✉ uday.hakari@gmail.com

ABSTRACT

Shales are fine-grained, laminated or fissile classic sedimentary rocks with predominance of clay and silt as the detrital components. They may be classified as clayey, silty or sandy shales on the basis of texture. Other criteria used in the classification of shales include mineralogical composition, cementing materials, organic matter content, depositional environment and strength. Generally, shales have moderate to high clay content, low strength, low permeability and are water sensitive. Apart from many uses, the shales are important to the petroleum industry because of their usefulness as source rocks in extraction of oil and natural gas, use as seals in petroleum traps and reservoirs. In the present paper, it is attempted to present the properties and uses of shales of the Dharwar system which is 4–1 billion years old and has special distinction of being the first and oldest metamorphosed sedimentary rock system in India. Because of its unpredictable behaviour, shales are found to be difficult rocks to classify, sample and obtain reliable test data for engineering purposes. The origin, distribution, classification, properties and the possible uses of shales of Dharwar system are briefly discussed and their engineering evaluation for construction also has been presented.

Keywords : Shales; Classification; Dharwar system; Composition; Oil and natural gas.

INTRODUCTION

Shale is a fine-grained sedimentary rock that forms from the compaction of silt and clay-size mineral particles which makes it fissile and laminated. This composition places shale in a category of sedimentary rocks known as mudstones. In fact, the shale can be considered as boundary material between soil and rock; which makes it typical for characterising its engineering properties. Hence Shales are considered as one of the problematic rock types for their applications in engineering domains (Farrokhrouz and Asef, 2013). In general, the shale is composed of quartz, feldspar and minerals. The major minerals in shale are kaolinite, illite, and smectite. Other minor constituents normally found are organic carbon, carbonate minerals, iron oxide minerals, sulfide minerals, and heavy minerals. Shales are the most abundant of all sedimentary rocks constituting about 60%, and are distributed over wide range of geologic ages. Their colours may range from white through green to grey and brown to black depending on their composition and environment of deposition (Boggs, 2009). The organic material of the shale offers prospects of oil and natural gas if pressured and properly heated after burial.

In this paper, the composition, classification, properties and uses of shales are presented with emphasis on their engineering evaluation. The shales of Dharwar system are considered in particular while illustrating the importance of this rock class.

Origin and composition of shales

Shales may form in any environmental condition in which sediment is abundant and water energy is sufficiently low to allow settling of suspended fine silt and clay (Porter et al, 1980). Silts and clays when newly deposited from suspension in water undergo compaction due to continuous accumulation of other sediments above them. The silt and clay percentage in the shales may vary but however at least 50% of their material is finer than fine sand. The transformation of soil into shale rock and the subsequent formation of metamorphic rocks depending on the mineral composition of the shale and degree of metamorphism is schematically indicated in **Fig. 1**.

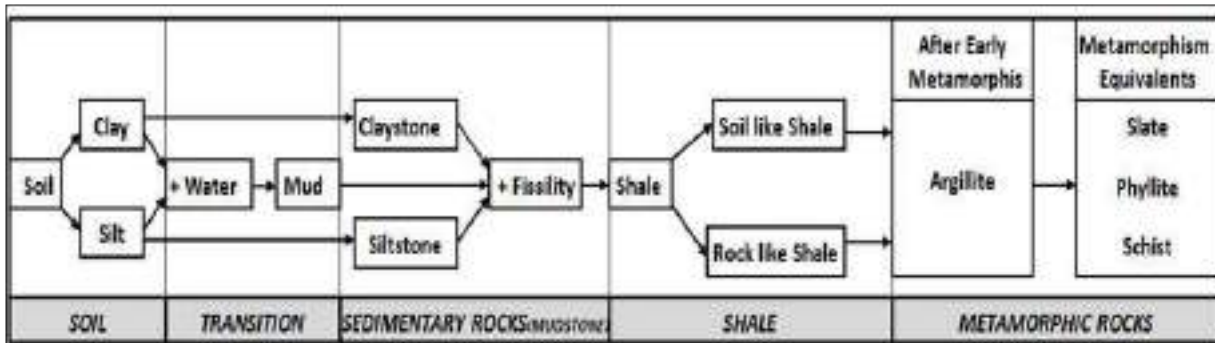

Fig. 1. Transformation of soil into shale and subsequent metamorphic rocks

Classification of Shales

Shales are fissile clastic sedimentary rocks formed from transportation, deposition and compaction of detrital materials of silt and clay. Fissility (the property of a rock to split easily along thin closely spaced [$< 10\text{mm}$] parallel layers) of the clay is the main characteristic of the shales which distinguish them from other sedimentary rocks. Shales can thus be classified based on the observable features and environment of deposition such as texture, mineralogical composition, type of cementation/cementing materials, depositional environment, organic matter content and strength (Boggs, 1995). Brief discussion on the classification of shales is presented below.

Texture

Shales characteristically contain fine-grained silt and clay particles. They are therefore classified as silty shale or clayey shale, depending on whether silts or clays dominate in the constituents of the rock. Silty shale and clay shale may collectively be called argillaceous shales.

Mineralogical composition

Shales may be classified as quartzose, feldspathic or micaceous shales depending on the predominant presence of minerals viz. quartz, feldspar or mica, respectively in the rock (Pettijohn, 1957).

Type of cementation/cementing materials

Shales like other sedimentary rocks are cemented by some minerals or elements after deposition and compaction. The cementing material may be used in the classification of the shales since the type of cementing material may affect the properties or performance of the shale when used as an engineering material. The cementing materials commonly found are silica, iron oxide and calcite or lime. Accordingly, the shales may be classified as siliceous, ferruginous or calcareous depending upon the predominance of the presence of silica, iron oxide and calcite or lime, respectively.

Environment of deposition

The environment in which sediments are accumulated and later get transformed into rock is a natural geographical process which can be considered as another valid base for classifying the shales (Reineck and Singh, 1980). Three sedimentary environments of deposition namely, continental, transitional or marginal and marine are prominently observed. Shales are generally deposited in lacustrine (continental), deltaic (transitional) and marine depositional environments and may accordingly be classified as lacustrine, deltaic and marine shales (Boggs, 1995). Lacustrine deposits are characterized by mixture of clay, silt, sands, inorganic carbonate precipitates and various fresh water invertebrate organisms as well as various plant deposits. Deltaic deposits are generally paralic i.e. consisting of orderly sequences of shales and sandstones. These deposits are also characterized by shallow depth and concentration of clay minerals such as kaolinite, illite and montmorillonite. Marine deposits are non-paralic and are characterized by homogenous rock sequences, great depth, oxygen deficiency, concentration of illite/montmorillonite, dark colour and considerable presence of marine fossils.

Organic matter content

Shales may be classified as carbonaceous or bituminous on the basis of their organic matter content (Krumbein and Sloss, 1998). The carbonaceous and bituminous shales generally contain more than 10% of organic matter which in fact induces black

or grey colour to the shales. When the dominant organic matter content in shales is from plant fragments such as pollen grains, stems and leaves, the shales are then classified as carbonaceous. When the dominant organic matter content in the shales is from animal fragments such as fossils, such shales are classified as bituminous. It is worth-noting here that, both carbonaceous and bituminous shales are important source rocks for generation of petroleum oil and gas.

In addition to the above criterion, the rock strength may be considered for classifying the shales, which can be fairly useful in evaluation of strength of shales. Likewise, colour of the shales, which in fact may be quite useful in understanding the composition of the materials forming the shales and suggesting its usefulness, may also form a base for classifying the shales. This is evident from the fact that, colour of the shale is often derived by the presence of specific materials composing it; for example, just a little presence of organic material or iron can significantly alter the colour of the shale.

The summary of the classification of shales is presented at **Table 1**.

Table 1. Criterion wise classification of shales

Sl.no.	Criterion	Classification
1	Texture	Silty shales, Clayey shales, Sandy shales
2	Colour	Black and Grey shales, Red, Brown, Yellow shales
3	Mineralogical composition	Feldspathic shales, Quartzose shales, Micaceous shales
4	Cementing materials	Calcareous shales, Ferruginous shales, Siliceous shales
5	Organic matter content	Carbonaceous shales, Bituminous shales
6	Depositional environment	Lacustrine shales, Deltaic shales, Marine shales
7	Strength characteristics	Soil-like or rock-like shales, Weak or Strong shales, Low strength or High strength shales, Low/ High modulus ratio shales, Soft/Plastic or Hard/Brittle shales

THE DHARWAR SYSTEM SHALES – LITHOLOGY AND DISTRIBUTION

Lithology

The term Dharwar has been derived from Dharwad district of Karnataka where these rocks were first discovered. The geological name for the crystalline schist near Dharwad is known as ‘Dharwar System’, the name being given by Robert B.F. who identified them way back in 1886. The Dharwar system is formed by lava, dust and other particles of volcanic origin and is made up of sedimentary rocks. This sedimentary system was believed to have been formed after granitoid gneiss rocks broke upon due to tectonic changes resulting in disturbance of sedimentation and formation of metamorphic rocks. These rocks are not found in their original horizontal manner, rather these have been greatly deformed by tectonic activities may be such as folding, faulting, tilting etc. And as such they have lost many traces of their sedimentary nature and have acquired crystalline and schistose structure. The weathering of the pristine Archaean gneisses and schists yielded the earliest sediments which were deposited on the bed of the sea, and formed the oldest sedimentary strata called the Dharwar system (Wadia, 1975). There are four types of rock system in this rock formation viz.(a) Igneous rocks, (b) Crystalline sedimentary rocks (c) Disfigured sedimentary rocks and (d) Incrusted Igneous rocks. The rocks of Dharwad schists are spread in north south direction as bands in different sizes. Surrounding this are found granite and gneiss rocks.

The Dharwar system shales are thus a complex of rocks- like classic sediments, chemically precipitated rocks, volcanic and plutonic rocks-which have been highly metamorphosed. The main rocks are schist, phyllites and slates. The schists are of various types: horn-blende schist, chlorite schist, magnetite schist, haema-tite schist, felspathic schist which are interbedded with quartzites, marbles, ophicalcites, banded jespars, beds of steatite, iron ores etc. These rocks are very much intruded by plutonic masses like nepheline- syenites, sodalite-syenites, tourmaline-granites, dunites etc. They occur in narrow elongated synclinal outcrops and are rich in miner-als. The structure of the Dharwar rocks shows no layerings and these are mostly found in tabular form.

Distribution

The Dharwar system of rocks occur in scat-tered patches in: (i) Southern Deccan, (ii) Central and Eastern parts of the Peninsula, (iii) Die north- western region, and (iv) The Himalayan region. The distribution of the Dharwar system shales in India is shown at **Fig. 2**. A brief description of these are presented in the following sections.

Southern Deccan

This includes the Dharwar region (presently called as Dharwad) of Karnataka state where these rocks have been found in abundance. These rocks occupy 15,540 sq. km. of area in Dharwad and Bellary districts of Karnataka and extend up to the Nilgiris, Madurai and Sri Lanka. Five prominent areas of occurrence of shales of Dharwar system have been identified (Naha et.al. 1993). They are Eastern, Eastern-central, Western-central, Central and West-ern belts. These rocks are divided into lower, middle, upper and post-Dharwar strata. Amongst these the lower Dharwar system are largely igneous, varying from acidic to basic. These are overlain by middle Dharwar system rocks consisting of quartzites, slates, conglomerates, horn-blende-schist, talc-schist, chart, iron-stone, marble and also some granite and porphyries. Numerous veins of quartz traverse these rocks. The rocks of upper Dharwars are predominantly sedimentary rocks, ferruginous, calcareous, siliceous and argillaceous, containing large quantities of iron and manganese ores. Rocks belonging to the Dharwar system are also found in Andhra Pradesh (Hyderabad, Guntur, Nellore), and Tamil Nadu (Arcot, Tiruchchirappalli).

Central and Eastern Peninsula

This is a large area spreading over the parts of the country in the states viz. Madhya Pradesh, (Balaghat, Chhindwara, Jabalpur), Maharashtra (Nagpur, Bhandara), Jharkhand (Ranchi, Singhbhum, Hazaribag), Orissa (Sambalpur, Keonjhar, Mayurbhanj) and West Bengal. The rock system here consists of main series viz. Chilpi Series, Sausar Series, Sakoli Series, Khondalite Series and Iron Ore Series.

North-Western Region

The Dharwar system rocks are found to occupy a wide surface area in Rajasthan and Gujarat states including the Aravalli Hills. These consist of the Aravalli system, the Raialo series and die Champaner series.

Extra-Peninsula

Outside Peninsula, the outcrops of the Dharwar system rocks are also found in the Meghalaya Plateau (die Shillong series in Kliasi and Jaintia hills), die Hima-layas (die Salkhala series in Gilgit, Baltistan, Ladakli, Keran and Kishtwar consisting of carbonaceous and graphitic shales, slates, phyllites, quartzites, schists, gneisses and marble).

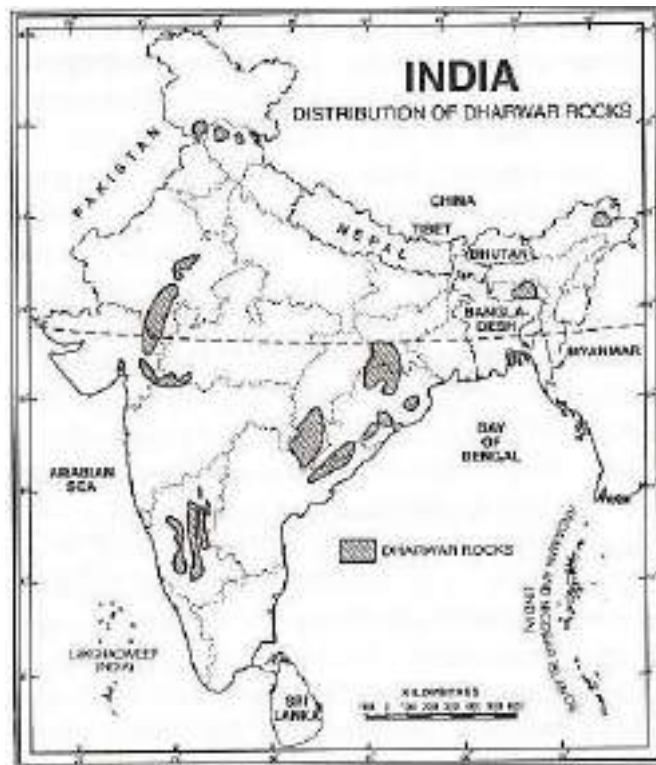

Fig. 2. Distribution of the Dharwar system shales over India

PROPERTIES OF SHALES OF DHARWAR SYSTEM AND THEIR EVALUATION FOR CONSTRUCTION

Shale in general is of interest with respect to its mechanical properties (Josh et al., 2012; Sondergeld et al., 2010). Deformation of soil and strength are critical for various stability problems. Horsrud (2001) noted the fact that the shales have certain characteristic features that make them difficult to handle correctly. The critical characteristics which make the shales problematic are low strength, high clay content, low permeability and sensitivity to contacting fluids.

Due to the varied nature of shales, the properties also vary for different shales. The index and geotechnical properties which are useful in the evaluation of shales as engineering material for construction have been determined. Table-II gives typical range of values of these properties. The desirable range of values of these parameters for the shales of Dharwar system are also given in the table along with their engineering evaluation (Waltham, 1994). The values indicated are based on the respective tests conducted as per the relevant IS codes for these tests. The evaluation offers further scope as well, for conducting few more tests viz. slake index test, slake durability index test, jar slake index test, point load test etc. and considering the values of these indices also for the evaluation.

Shales of Dharwar system and the soils derived from them are considerably problematic materials from the point of view of construction upon them. They are subject to changes in volume and competence that generally make them unreliable construction substrates. As can be seen from the Table-II, the shales of Dharwar system exhibit moderate to poor geotechnical characteristics to be considered as engineering material for construction. The clay minerals in some shale-derived soils have the ability to absorb and release large amounts of water. This change in moisture content is usually accompanied by a change in volume which can be as much as several percent and hence they exhibit the nature of expansive soils. When these soils become wet they swell and when they dry out they shrink. Buildings, roads, utility lines or other structures placed upon or within these materials are likely to get weakened or damaged by the forces and motion due to volume change. Owing to their poor shear strength, these shales are often associated with landslides. Weathering transforms the shale into a clay-rich soil which normally has a very low shear strength - especially when wet. When these low-strength materials are wet and on a steep hillside they can slowly or rapidly move down slope. Overloading or excavation by humans may also often result in failure. Shales of Dharwar system are hence considered to be one of the bedrocks that give potential problems for construction. As the overburdened load is removed during excavation, the rebound of the sides and bottom of the excavation in the bed shales causes the problem which is commonly faced. Swelling during monsoon deforms structural members or structural elements of engineering works in shale mass. Swelling of shales is a common problem for highways constructed in cut and fill situations. Shrinkage develops fractures along existing micro-cracks, thus degrading shear strength, and increasing hydraulic conductivity in rock mass. From the hydraulic conductivity point of view, these shales are impermeable except where silt or sand occurs in alternating layers within the shale mass. When these shales are weathered, it breaks and slakes easily. They slake almost immediately when exposed to air, which causes a problem during construction of tunnel and other underground openings in shale mass. The shales of Dharwar system and the soils derived from them, thus exhibit nearly similar behaviour as that of clayey or black cotton soils. There are some properties of these shales which are desirable even though these rocks are problematic for engineers and designers. For example, these shales can govern the hydraulic conductivity that controls movement of ground water by acting as a barrier. From excavation point of view, it is easily excavated and seldom requires ripping and almost never requires drilling and blasting.

USES OF SHALES OF DHARWAR SYSTEM

Shales of Dharwar system exhibit certain special properties that make them useful resources. Some of the possible uses of these shales are briefly mentioned below, which may open up scope and prospects even for exploring oil and natural gas, apart from yielding certain minerals

Clay Products

Shales of Dharwar system prove useful in forming the clay. As it is known, many products such as bricks, tiles, pots etc. are normally made from natural clay. However, such enormous and incessant use has resulted in depletion of most of the clay deposits, necessitating the need for a new source of similar raw material. Mixing finely ground shale with water would produce clay that often had similar or superior properties as that of natural clay. As a result, many of clay products that were once produced from natural clay have been replaced by almost identical items made from clay manufactured by mixing finely ground shale with water.

Table 2. Range of values of index and geotechnical properties of Shales of Dharwar system shales and their engineering evaluation

Sl. no.	Parameter	Typical Range of values for shales	Desirable range of values for construction	Average value of Shales of Dharwar System	Evaluation of Shales of Dharwar System as engineering material for construction
1	Natural moisture content (%)	20 - 34	5 - 20	18	Marginally acceptable.
2	Dry density (kN/m ³)	1.12 - 1.78	1.8 - 2.5	1.60	Marginally acceptable / Indicative of moderate strength.
3	Activity ratio	0.75-2.0	0.35 - 0.75	0.65	Highly Plastic. Acceptable but high volume change is expected
4	Predominant clay mineral	Illite/ Montmorillonite	Kaolinite / Chlorite	Montmorillonite	Unfavourable / High swell-shrink character expected.
5	Swell potential (%)	3 - 15	1 - 3	4.2	Unfavourable / High swell potential
6	Coefficient of Permeability (cm/ sec)	1x10 ⁻⁵ - 1x10 ⁻¹⁰	>1x10 ⁻⁵	0.85x10 ⁻⁵	Marginally acceptable / Poor drainage property expected.
7	Angle of internal friction (degrees)	10 - 20	20 - 45	18	Unfavourable/ Indicative of low shear strength and low bearing capacity.
8	Cohesion (kN/m ²)	35 - 700 kN/m ² (3.5-70 t/m ²) (35-700 KPa)	700 - 10000	32	Critical / Indicative of low bearing capacity.
9	Unconfined Compressive Strength (UCS) (kN/ m ²)	340-2070 kN/ m ² (0.34-2.07 MPa)	2000 - 35000	3600	Marginally acceptable but critical / Indicative of poor strength characters.

Cement

These shales offer scope to produce cement as well, by crushing the shale and lime stone and then heating to a temperature that is high enough to evaporate off all water and break down the limestone into calcium oxide and carbon dioxide. The carbon dioxide is lost as an emission but the calcium oxide combines with the heated shale and results in a powder which is similar to cement and which gets hardened when mixed with water and allowed to dry. Such cement can be used to make concrete and many other products for the construction industry. This is another area that offers scope for the possible commercial exploitation of the abundant deposits of shales of Dharwar system.

Hydrocarbons

Liquid and gaseous hydrocarbons can be extracted from oil shale which contains significant amounts of organic material in the form of kerogen (a mixture of hydrocarbons from deceased plants and animals). But the rock requires to be heated and/ or treated with solvents. This is usually much less efficient than drilling rocks that will yield oil or gas directly into a well. However,

extracting the hydrocarbons from such oil shales produces emissions and waste products that cause significant environmental concerns and this fact may be the reason for

the world’s extensive oil shale deposits not being aggressively utilized.

Oil and natural gas

The black organic shales of Dharwar system are the source rocks for oil and natural gas deposits. These black shales obtain their black colour from tiny particles of organic matter that were deposited with the mud from which the shale formed. As the mud

was buried and warmed within the earth, some of the organic material was transformed into oil and natural gas, which then get migrated out of the shale and move upwards through the sediment mass because of its low density. The oil and gas are often trapped within the pore spaces of the rock unit which then easily flow into the extraction well as in case of a conventional oil/gas reservoir. Although large amounts of oil and natural gas can be extracted unconventionally from the reservoir rock by way of drilling, much of it remains within the shale and this oil and gas is very difficult to remove because it exists trapped within tiny pore spaces or adsorbed onto clay mineral particles that form the shale.

In the late 1990s natural gas drilling companies developed new methods for liberating oil and natural gas that is trapped within the tiny pore spaces of shale, and this was significant achievement which led to unlocking of some of the largest natural gas deposits in the world. However, steps in the direction to explore oil and natural gas from the shales of Dharwar system are yet to be initiated and their importance to the petroleum industry is yet to be established. Large scope thus exists to carry out the explorative works on shales of Dharwar system.

CONCLUSIONS

In the literature only a few studies are available that have been focussed and exclusively carried out on Dharwar system shales. Based on the limited horizon of the study carried out in this work, following broad conclusions are drawn. It may be noted that, the Dharwar system rocks offer a great scope further for elaborate studies particularly pertaining to their possible commercial exploration.

- i) Shales of Dharwar system are fine-grained laminated sedimentary rocks with silt and clay as predominant detrital particles. Other major constituents include organic matter and cementing materials. The minerals contained in these shales are distributed in the silts, clays, cementing materials and organic matter.
- ii) Clays and quartz are the main minerals constituting these shales. The other common minerals of these rocks include feldspars, calcite, mica, pyrites, iron oxides and organic carbon.
- iii) Texture, mineralogical composition, cementing materials, organic matter content, depositional environment and strength criteria can be considered for classifying these shales. They are found to vary in colour ranging from white through red and green to grey and black depending on mineralogical composition and depositional environment. They are water sensitive with low strength and low permeability.
- iv) The Dharwar system shales exhibit poor to moderate geotechnical properties and their engineering evaluation indicates that these rocks as well as their derived soils are considerably plastic in nature, weak in strength and hence are considered as problematic substrata for construction.
- v) The occurrence of black shales of Dharwar system can be found as source rocks, and reservoir rocks for prospecting oil and gas. These rocks may also offer prospects for being explored to manufacture clay products, cement and gaseous hydrocarbons.

Maintenance of PMGSY Roads in India

Sandeep K Shrivastava

Professor and Head, Civil Engineering Department, OIST, Bhopal

✉ joisthodce@oriental.ac.in

ABSTRACT

PMGSY is a nationwide plan with a view to provide all weather connectivity to remote rural villages which are unconnected to main road so far. This centrally sponsored scheme has launched by the PM Late Shri A. B. Vajpayee in 2000, 20 years ago with the aim to provide roads to all villages in rural India and by 2020 it is expected hundred percent connectivity will be achieved. Looking to the huge stock of rural roads the roads needs proper maintenance for smooth traffic facility to rural habitat to have optimum service in roads. This is in general the maintenance of roads are done by government Agencies but introduction of private contractors needed in present situation. The ownership of PMGSY road cluster connected to main road of particular chainage/KM awarded to private contractors for maintenance of roads for specified period.

Keywords : Agencies, maintenance, PMGSY, service, scheme, ownership.

INTRODUCTION

Maintenance of roads continues to be responsibility of Government agencies in India. The quality of road network remains as a subject of concern not only to Government department but also to as well road users. Proper maintenance of PMGSY road network & construction to adduces the long sharing public demand involves large investment & public money and are one of the most important public utility. There is a need to use better road construction & maintenance techniques and as well as ensuring accountability by the agencies involved in this existing conventional system of road maintenance by Government agencies should be worked and remained to explore the possibilities of introducing novel avenues such as innovative contracting procedure term contract to wide a few to treasure these possibilities near long lengths of time.

Aspects of Maintenance

The maintenance of PMGSY Road can be broadly classified in the following subheads

1. Ordinary Repairs
2. Renewal and Resurfacing
3. Special Repairs such relates to curves or of damaged CD works
4. Emergency repairs due to natural calamities such as floods, landslide and so on.
5. Routine Repairs

Fig. 1. PMGSY Road – Poor Maintenance

Contract Maintenance Procedure

PMGSY scheme can take up some pilot level projects for the maintenance of roads by involving private entrepreneurs. The task of maintenance of given roads connected between Chainage of main highways. The design and minimum levels of serviceability can be given on contract. It is suggested that an innovative contracting procedure be prepared for the maintenance of such PMGSY roads connected between chainage of NH and highways with minimum serviceability period fixed between 5 to 10 years. Before bidding the agency has to evaluate the structure and functional condition of pavement, condition of shoulders, drainage measures should bid for the contract to maintain the routes. It is suggested that a single contract incorporating all maintenance items should be feasible. This method of contracting would significantly reduce the contract administration cost.

Issues

Majority area of pavement section in PMGSY roads have inadequate crust thickness and poor subgrade and surface drainage facilities under these making it is very difficult to predict the future performance level of pavement.

There are uncertainties regarding the budget allocation for maintenance of PMGSY roads.

The roads of five years or so old there is a absence of maintenance record of road i.e. maintenance history of PMGSY roads are not known.

Due to heavy traffic and overloading the point is that why roads would fail much earlier than the anticipated design traffic.

Advantages of contract management

The firm which has to maintain a minimum level of serviceability has to use better materials, better methods or Constructions, employing the staff available for the maintenance and machinery. The private firm taking the responsibility of preventing premature failure of roads due to overloading and heavy rains. The PMGSY roads will become more safer as there will be proper sign boards markings and will be maintained by firm. May firm will be responsible of mainting the riding quality of during its serviceability time. There are number of problems of maintenance such as minor changes, rain water drains and repairs of CD works.

On the project maintenance contract for which the contractor established an appropriate quality system the PMGSY department engineer has to perform the audits of system like inspection of work and random sampling of materials used in maintenance of roads there by limiting the role of PMGSY engineers, there will be an objective evaluation of road condition in terms of riding quality, problems of subjective assessment are eliminated such as condition of road surface physical condition of culverts & minor bridges condition of shoulders etc.

CONCLUSIONS

The problem of poor condition of PMGSY roads in India cannot be solved by enhanced allocation of funds for maintenance alone, effective utilization of funds can be realizes by the inclusion of private sectors and by innovative contract procedures.

The problem of higher maintenance cost of PMGSY roads can be managed by private entrepreneurs to develop commercial establishments at the suitable junctions of NH to PMGSY road of government land generate funds from shops, from stipulated time period of 5 to 10 years and maintain the PMGSY roads cluster under these particular Chainage of NH there by reducing the budget allocation of maintenance of roads.

The NGO of young engineers can be involved in the maintenance of PMGSY roads to reduce the unemployment. The promotion of self help groups of locals comprising of team of Engineers willing to undertake maintenance of PMGSY Road can be improve their proposals.

An innovative contract procedure of professional employment can result in lower overhead costs and direct cost to the government.

In the end it could be summarised at the maintenance of PMGSY roads through contracts 5 to 10 years needs to be tried on extensive scale in their of privatization where large role is contemplated for private entrepreneurs

Way Forward to Enhancing Skills for Betterment of Indian Economy through Construction Industry

Sekar Kumbeswara

Chief Engineer & Administrator, ALHW (Retd.) Ministry of Shipping, GOI

✉ ksekar_alhw@yahoo.com

ABSTRACT

The construction industry in India is one of the prime contributors towards the economic development of India. There has been inordinate delays in project implementation thereby resulting in cost-over-run. Reasons behind such delays, solutions and way forward are discussed in this paper.

Keywords : Project management; Ease of doing business; Factors delaying projects; Self-reliant India; Unfair clauses.

INTRODUCTION

The Construction industry of India is an important indicator of the development of India as it creates investment opportunities across various related sectors. With a share of around 9%, the contribution of construction industry to the national GDP at factor cost in 2011–12 is estimated as ₹670,778 crores (US\$ 130 billion).

In the report of Ministry of Statistics and Program Implementation, Government of India it is stated that out of 782 construction projects in India monitored by it, a total of 215 projects are delayed from 1 to 261 months of time-overrun. The primary causes which are noted are delays in land acquisition, obtaining forest/environment clearances, tie-up of project financing, finalization of detailed engineering, tendering, ordering and equipment supply, lack of infrastructure support and linkages, ordering and equipment supply, changes in scope, geological surprises, delay in tendering, , law and order problems, and contractual issues.

Major impact of delays

1. Delays in projects causes a direct impact on the overall cost of project. For example, from 2010 to 2015, the cost of cement (per bag) increased by 74%, steel increased by 34%, bricks increased by 69%, sand increased by 240% and skilled labor (on a per day basis) increased by 96%. It is therefore, understandable, that the cost overrun in delayed projects has resulted in approx. 24.77% increase in the original cost of the projects, amounting to Rs. 1, 09,359crores.
2. The likelihood of disputes between the parties in a contract increases multifold and these disputes may derail the project. A statistics show that the average duration for settlement of disputes is more than 7 (seven) years in India.[1]

Over the past few decades, there has been several big-ticket infrastructure projects launched in India, investing billions into the country's aviation, industrial development, railways, roads, smart cities and energy sectors. The most recent available Flash Report of September 2018 published by the Ministry of Statistics and Planning

states that out of 1,420 central-sector infrastructure projects worth Rs 1.50 billion and above, 385 are on schedule, 366 projects delayed, 358 projects reported cost overrun, and 136 projects are both time and cost overrun. Around 32 mega projects have reported additional delays vis-à-vis their date of completion. [2] The predominant reasons for delays in project completion are:

- 1) Lack of expertise in project planning and management by the project authorities
- 2) Environment issues
- 3) Insufficient data collection and analysis before formulation of detailed Project report
- 4) Change in Government laws
- 5) Bureaucracy of the Government officials and Corruption
- 6) Frequent Change Orders

- 7) Poor estimation without consideration of steep escalating costs
- 8) Inadequate funds flow for the project
- 9) Lack of knowledge of updated technology by project authorities which leads to wrong planning and varying costs
- 10) Unfair and one sided substandard contract clauses

Prime Minister Narendra Modi's administration has drawn up a plan for an estimated cost of \$1.5 trillion of such projects over five years. But delays in land acquisition, environment clearances, and financing are among issues that have held up projects over the years -- a big worry for multilateral investors when it comes to funding projects in India. [3]

The reason for this worry is quite justifiable as the investors are worried about the unfair clauses in the construction contracts, especially those executed by departments under state or union governments in India.

It is highly imperative that India needs to move faster on the reforms front and to lure global investments. The available data suggests that the resources required for starting a business can be considerably higher in the lower income economies. Improving the conditions for "Ease of Doing Business" (EoDB) rankings have been a great opportunity to improve India's internal processes and structural changes and make them business-friendly. This could give an edge of benchmarking India, on common parameters, with the rest of the world. In fact, with competition among countries hotting up, EoD Rankings have become the sole biggest value proposition to attract investment.

Sectors like rail, road, transport, steel and cement are crying for such reforms. The priority reforms which are demanding are-enforcing contracts, registering property, starting a business, and paying taxes For example, for enforcing contracts during the year 2019, India's rank was 163rd among 190 economies which implies much time and cost overruns in resolving commercial disputes, which is certainly not conducive for a thriving business environment.[4]The way forward is to carry out long pending reforms of judicial systems in India. A slew of small, but bold, decisions, which may not even be politically fashionable, offer a great opportunity to make a lasting difference.

Recently, as a part of the government's economic stimulus package announced under AtmaNirbhar Bharat Abhiyan, the Government of India has decided to bring various amendments to Insolvency and Bankruptcy Code and Companies Act, 2013 to enhance ease of doing business in the country. The vital areas where India should invariably do a lot of progress and to improve score on Ease of Doing Business are the six parameters- enforcing contracts (163rd), resolving insolvency (52nd), starting a business (136th), registering property (154th), paying taxes (115th) and trading across borders (68th) where it has been scoring very low.[5] Though it is a tough job to improve on these pointers, it is a must that stringent actions are to be taken to regulate them through judicial reforms.

Project related activities-Problems and Solutions

It is very important to identify and spot the project failures before they actually happen. The following are the indicators to such disasters.

- 1) When the stake holders show lack of interest by not turning up for meetings and discussions. If stakeholders stop caring about a project, it is high time to 'hold a sit-down' to determine the current perceived value of your project to the organization.
- 2) When there is poor communication. The best Project manager spends 90% of his time on communication with his team, stake holders and project authorities. Fast, automated and efficient communication system should be ensured.
- 3) When honesty about the velocity is lost. There cannot be any delay in approvals or decision making on problems. The Project Managers should be so capable of facing the bottleneck at lightning speed and hence they should have proper training, education, will and drive to face the situation daringly.
- 4) No-Bad News Situation shall prevail. This is possible only if a proper and instant tracking system of all activities is in place and monitored closely by the monitoring team of the Project manager.
- 5) Minimize Scope Change. This is possible only when proper investigations are done before formulation of the project by abundant data collection, analysis. When this is done stupendously, the design of project becomes near perfect which renders almost correct estimation. A good project Manager with the support of a good management can draw a balanced tender document which is the key for completion of project without time or cost-over run.

It is high time to see certain examples of poor planning and lack of project management ideas.

- 1) Gujarat International Finance Tec (GIFT) City that is planned on 886 acres of land near the Ahmedabad airport as a 50:50 joint venture between International Leasing and Financial Services (ILFS) and a state government firm. The 78,000 crore project is caught in red tape.[6] Several buildings being left incomplete with power supply yet to be made available due to lack of clearances. In addition to this delay, permission to lay the underground power cables to the city has not been obtained from the National Highways Authority of India (NHAI). And to top it all, due to lack of norms of operating procedures, the project has not been able to attract a single client to set up operations. This is a clear example where the project is announced first and clearances applied for later.
- 2) In Sept 2011, Delhi received a massive amount of rainfall as a result of a cloudburst. As a result, a part of T3, the spanking new airport terminal, was under ankle deep water, parts of the roof leaking profusely, the underpass leading to the airport under 4 feet of water. Basically, the brand new airport was in a state of partial shutdown and a total mess. This is a glaring case of poor vision, poor planning, bad design and poor execution.

Way Forward to improve Project Management Techniques

An area of project management that requires the greatest improvement is the definition of explicit, realistic, immediate, and long-term development objectives. The success for any project is possible only when objectives are understood and accepted by all participants in project administration. Knowledge in proactive risk management associated with the scope, schedule and cost of the project is extremely demanding for the entire project management team.

Developing countries like India require two types of trained and expert project administrators:

- i) who can plan and coordinate the entire project cycle as an integrated process and
- ii) who can manage the project as an organizational entity once it is selected and approved.

Most importantly, the needs of the “client” should be kept in mind on priority while improving project management techniques. Any new designs that violate the social, cultural, political and organizational traditions of developing countries simply will not work. Techniques must be developed which are sensitive to national needs, available resources, constraints and opportunities. These techniques must take advantage of the experience of local officials who know best what will work or will not work in their own countries.

Need for Fair Conditions in Construction Contract Documents

The most important reason for the poor response of global tendering in India is that in most of the tenders, the vital conditions are one sided and unfair. They are mostly a “Take it or Leave it” type of documents. Such tenders and contracts invariably lead to disputes and end up with arbitration and litigation thereby the parties are put to heavy loss apart from inordinate delays in project completion and cost overrun.

Some examples of unfair clauses in the contracts are elucidated below:

- 1) Clause (22) Conditional/ Incomplete tender will not be accepted. (Tender Ref. No: WBPWD/EE/BED/41/e-IT of 2019_20_3rd call)

It is understandable to reject incomplete tenders but not conditional tender. Conditions arise only when details or data provided in the tender documents are truncated or insufficient. This means that the project authorities have not done proper home work to collect all relevant data to suffice requirements.

- 2) “No claim for interest or damages will be entertained by the Government with respect to any money or balance which may be lying with the government or may become due owing to any dispute, difference or misunderstanding between the Engineer-in-charge on the one hand and the contractor on the other hand or with respect to any delay on the part of the Engineer-in-charge in making periodical or final payment or in any other respect whatsoever” which is unfair.
- 3) Under the general law of contracts, once the contract is entered into, any clause giving absolute power to one party to override or modify the terms of the contract at his sweet will or to cancel the contract – even if the opposite party is not in breach, would amount to interfering with the integrity of the contract.
- 4) A clause in a contract debarring the contractor from claiming escalation in rates has been construed to be limited only up to the stipulated period of contract and not beyond.
- 5) One sided clauses providing for unlimited variation in quantities and unfair interpretation of variation clauses have been set

aside by the Courts by holding that the Engineer-in-charge cannot require a contractor to execute additional work without any limit and that a reasonable limit should be placed on the quantity of additional work, which the contractor may be required to execute at the rate stipulated for the main work under the contract.

The Standard form contracts of the government departments and PSUs are usually pre-printed contracts that are only “contracts” in name. The standard terms and conditions unilaterally prepared by one party are offered to the other on a take it or leave it basis, rather, the terms are forced on the other party. When the party having greater bargaining position has introduced exemption clauses unilaterally in its own favor, the courts have no other option but to give full effect to those unreasonable or unconscionable clauses which have been agreed upon and signed by both parties in accordance with the current laws in force.

With a view to reform this lacuna, the Law Commission of India in its 103 Report suggested that an additional Section 67A be added to the Indian Contract Act, which reads as follows:

“67A. (1) Where the Court, on the terms of the contract or on the evidence adduced by the parties, comes to the conclusion that the contract or any part of it is unconscionable, it may refuse to enforce the contract or the part that it holds to be unconscionable.
(2) Without prejudice to the generality of the provisions of this Section, a contract or part of it is deemed to be unconscionable if it exempts any party thereto from – (a) the liability of willful breach of contract, or (b) the consequences of negligence.”[7]

The 199th Report of Law Commission of India on UNFAIR (PROCEDURAL & SUBSTANTIVE) TERMS IN CONTRACT submitted to Government of India during August, 2006 states as, “Our business and commerce will be put to serious disadvantage if we do not have a law regulating unfair terms of contract.....Therefore, it has become necessary to provide additional provisions in India for redressal against unfair terms of contracts”. [8] The highlight of this Report is the consideration of Unfair Terms of Contract by separating the ‘procedural unfairness’ and the ‘substantive unfairness’ in the matter of contracts or their terms and strengthening the recommendations of the Law Commission report 103.

What is proposed in this Report and the Bill is to provide additional provisions of ‘procedural unfairness’ and ‘substantive unfairness’ and remedies for removing such types of unfairness. These new remedies can be granted by the Civil Courts, arbitral tribunals and the consumer fora under the Consumer Protection Act, 1986 in addition to what has already been provided for in The Indian Contract Act, 1862.

“Section 16 ‘Undue influence’ of Indian Contract Act, 1862 defines: (1) A contract is said to be induced by ‘undue influence’ where the relations subsisting between the parties are such that one of the parties is in a position to dominate the will of the other and use that position to obtain an unfair advantage over the other.

- (2) In particular and without prejudice to the generality of the foregoing ..., a person is deemed to be in a position to dominate the will of another –
- (a) When he holds a real or apparent authority over the other or where he stands in a fiduciary relation to the other; or
 - (b) Where he makes a contract with a person whose mental capacity is temporarily or permanently affected by reason of age, illness or mental or bodily distress.”
- (ii) Subsection (3) of sec 16: The other relevant provision is sub-section (3) of section 16 which refers to the aspect of burden of proof in ‘unconscionable transactions’ induced by ‘undue influence’. Sub section (3) of section 16 and illustration
- (c) Are reproduced as under:-

“16(3) Where a person who is in a position to dominate the will of another, enters into a contract with him, and the transaction appears, on the face of it or on the evidence adduced, to be unconscionable, the burden of proving that such contract was not induced by undue influence shall be upon the person in a position to dominate the will of the other.

Nothing in sub section shall affect the provisions of section 111 of the Indian Evidence Act, 1872.”

Though countering and beating of these unfair clauses in the contract is being pushed for approval of the government for more than two decades, it is unfortunate that no fruitful results have emerged yet. It is high time that this should be taken up by competent forums with the Government which will go a long way in achieving the goals of the country in reaching to top slots in the global survey of “Ease of Doing Business” which will create tremendous potential of FDI, thereby uplifting the economy.

RECOMMENDATIONS

- 1) The contract documents for infrastructure projects should be standardized in line with FIDIC MODEL contract forms for all major contracts. This should be enforced in all construction departments of Governments.
- 2) Lack of Project Management techniques with the project authorities and construction agencies is a major problem and bottleneck causing delays in completion of projects. Hence, it is imperative that all such authorities should be trained suitably in Project Management techniques through workshops, seminars, training programs etc.
- 3) Project Management should be introduced as a part of core subject in the curriculum of under graduation streams with special post-graduation stream for the same including Risk Analysis and management so that there is no dearth of Project Management expertise in this country.
- 4) The recommendations contained in the Law Commission Report of 2006 in this regard of unfair clauses should be passed and promulgated without further delay.
- 5) Red tapism in bureaucracy should be curbed to the maximum extent and transparency brought in.
- 6) All clearances to be under single-window- system.
- 7) Necessary and adequate judicial reformation should be brought in expeditiously. Promotions to Engineering cadre to Group A positions in government departments shall be made on selection basis by scrutiny of their integrity, attitude, aptitude, knowledge, shrewdness to tackle unexpected situations by way of test, examination and personal interview etc. without any favoritism or politics.

CONCLUSION

For achieving the ultimate goal of raising the country as a leading economy in the world, it is essential that proper and sincere introspection by each and every citizen of this country, especially Engineering and project Management fraternity is a must. The government, having committed to reforms, should work in the directions suggested in this paper by giving a serious consideration. As per the proverb, “If there is a will there is a way”, what is all the more desired now is the “WILL” to enhance the skills, quality and safety to promote India as a self-reliant country.

Fibre Reinforced Geopolymer Concrete as a Repair Material for Rigid Pavements-A Review

Peter Cibi*, Karthi Lathi

Department of Civil Engineering, ToCH Institute of Science and Technology, Kochi, Kerala

*✉ peter.cibi@gmail.com

ABSTRACT

Concrete is a durable construction material, yet it is susceptible to distresses and deterioration. Numerous concrete repair systems are available with repair materials comprising of either cementitious types or polymer-modified cementitious types. The focus on sustainability in present times makes the use of cementitious based repair materials undesirable and hence the search for a sustainable and durable repair material is very relevant. Geopolymer concrete repair materials have gained considerable interest in this regard. Geopolymer is relatively a new construction material which could be produced by the chemical action between alumino-silicate material such as fly ash or blast furnace slag and alkaline solutions like sodium silicate or sodium hydroxide. They generate 70-80% less carbon dioxide than concrete made with ordinary Portland cement, making them ideal in aspects of both sustainability and durability for repair. In this paper, the focus is on the use of geopolymer based repair materials for rigid pavements. Concrete pavements undergo various types of distresses and damages during its lifetime such as damages in joints, shrinkage cracking, corner breaks, punch out, linear cracking, durability cracking and so on. Fibre reinforced geopolymer concrete which have proved useful as a repair material for different construction purposes due to its improved tensile characteristics and crack control properties are promising sustainable and economical solution to pothole repair for both flexible and rigid pavements. The enhanced bonding between the concrete substrate and better durability properties of fibre reinforced geopolymer concrete are ideal properties to be considered as repair material for rigid pavement. This paper reviews the literature related to the various studies conducted on fibre reinforced geopolymer concrete and the repair materials for rigid pavements with the purpose of finding common ground in both.

Keywords : Geopolymer concrete; Alumino-Silicate; Rigid pavements; Alkaline solution; Polypropylene.

INTRODUCTION

Deterioration in infrastructure and its repair and rehabilitation is one of the major challenges of modern construction industry that civil engineers face nowadays. The deterioration of concrete includes the loss in compressive strength, cracks formation and increase in porosity. Repairing concrete is one of the emerging sectors in construction industry. There are numerous methods and techniques for concrete repair and a wide variety of repair materials are available in the construction field. The two types of materials for concrete repair are cementitious and polymeric. The cementitious materials include materials based on portland cement, blended cement and rapid hardening cement. Among polymeric materials, one type is polymer modified concrete, in which latex, water soluble polymer or liquid polymer are mixed with an ordinary portland cement (OPC). Another type is polymer concrete which makes use of a polymer binder for the aggregates without using OPC. The selection of repair materials depends on factors like rapid setting, high flexural and compressive strengths, bond strength to the substrate, low drying shrinkage and similar modulus of elasticity as the substrate and low compressive creep. The major draw backs in selecting cementitious repair materials are low tensile strength and low durability problems like chemical attacks such as alkali -silica reaction, acid attack and sulphate attack, which in turn lead to corrosion and deterioration of the concrete structure. They are also not sustainable due to the fact that the major component is cement and manufacturing 1 ton of OPC releases around one ton of carbon dioxide (CO₂).

The focus on sustainability in present times motivates research in sustainable repair material. Geopolymer concrete (GPC), first introduced by Joseph Davidovits [15] is desirable in this regard. It is created by the reaction of alumino silicate binders such as fly ash (FA)/ground granulated blast furnace slag (GGBFS)/metakaoline (MK) with the alkaline solutions like Na₂SiO₃ /sodium hydroxide (NaOH). Geopolymer cements cure more rapidly than portland cement based concrete. Most of the compressive strength is gained within a day. Geopolymer binder production releases 80-90 % less CO₂ than OPC and usage of waste

industrial byproducts such as fly ash and ground granulated blast furnace slag make geopolymer a green material. Though the cost of producing geopolymer binder is higher than that of manufacturing OPC, it can be reduced by selecting the nearest source of feedstock thereby reducing the cost of transportation of raw materials. This paper reviews the use of geopolymer based repair materials for rigid pavements.

There are two types of pavements based on design considerations i.e. flexible pavement and rigid pavement. Difference between flexible and rigid pavements is based on the manner in which the loads are distributed to the subgrade. Flexible pavement can be defined as the one consisting of a mixture of asphaltic or bituminous material and aggregates placed on a bed of compacted granular material of appropriate quality in layers over the subgrade. A rigid pavement is constructed from cement concrete or reinforced concrete slabs. The rigid pavement has rigidity and high modulus of elasticity to distribute the load over a relatively wide area of soil.

Rigid pavements undergo various types of distresses and damages during its life time such as spalling, shrinkage cracking, corner breaks, punch out, linear cracking, durability cracking etc. The main techniques used for rigid pavement repairs are full depth repair, partial depth repair, diamond grinding and retrofitting dowels. Partial depth repairs are performed if the deterioration is within (1/3) rd of pavement slab thickness. It is deployed if the patch is of size 300mm X 100mm in area. The repair materials used are either normal setting plain cement concrete (PCC), high early strength PCC, rapid strength developing materials such as epoxy resin mortar or epoxy concrete. A “green” alternative for the rigid pavement repair could be fibre reinforced geopolymer concrete (FRGPC).

FRGPC has excellent flexural properties, crack control and toughness. There are numerous fibres compatible with geopolymer binder. Poly vinyl alcohol (PVA) fibres are highly stable in alkaline environment and show good bond to geopolymer binders but cost of PVA fibres are high. Steel fibres are relatively cheaper and exhibit excellent toughness. Addition of polypropylene (PP) fibre up to a limit of 2.5% by volume of binder increases the mechanical properties of GPC. For instance, adding PP fibres to Fly ash based GPC increases the ductility of the resulting compound. The presence of fibre in the geopolymer matrix makes the mix stiffer but this could be well compensated with addition of suitable super plasticizer. FRGPC excels in fire resistant properties and resistance to sulphate attack. It is used for constructing underground structures with outstanding mechanical, durability and shrinkage properties compared to OPC concrete with 70 % less carbon emissions.

In summary, the enhanced mechanical properties, less shrinkage and durability properties of FRGPC make it an excellent contender as a repair material in the current market. The addition of calcium compounds or slag based geopolymer can reduce the setting time. The incorporation of PP fiber in to GPC resulted in improved tensile characteristics, crack control, bond strength to the substrate and increased durability properties particularly with outdoor heat exposure (OHE) cured composites. Geopolymer cement is widely used for the construction of rigid pavements in North America for the last three decades under the brand name Pyrament© [14]. Thus FRGPC could be used as a sustainable and economical solution to pothole repair for both flexible and rigid pavements.

LITERATURE REVIEW

Turner L K et al. [37] compared the carbon dioxide equivalent (CO₂-e) emissions between GPC and OPC concrete. They found that 76.4 % CO₂-e for the OPC concrete. GPC shows comparatively 9 % less emissions than that of GPC. If the GPC is made with blended binders such as GGBFS and fly ash, CO₂-e emissions could be reduced by 19%-29 %.

Palomo A et al. [7] studied about the alkali activated fly ashes as a “cement for the future”. Class F fly ash was used for the experiment. The activators used are 12M NaOH, 18M KOH, Na₂SiO₃ + NaOH pellets and Na₂SiO₃ + KOH pellets. The alkali activation reaction of fly ash takes place as an exothermic process of dissolution, during which the breakdown of the covalent bonds Si-O-Si and Al-O-Al in the silicon and aluminum then pass into the solution. The reaction results in a poorly ordered structure with good mechanical strength. The curing temperature influences the gain in strength of the compound. Alkaline solutions containing soluble silicates increase the rates of reactions than solutions containing hydroxide. The binder to activator ratio was not so significant in strength development of the compound.

M Komljenovic et al. [25] studied about the mechanical and micro structural properties of alkali-activated fly ash geopolymers. The investigation made use of class F fly ash and the alkaline activators used were Ca(OH)₂, NaOH, Na₂CO₃, KOH, Na₂O•nSiO₂ (Aqueous solution of Na₂SiO₃ – water glass, n = SiO₂/Na₂O = 3.04.). The highest compressive strength was found when Na₂SiO₃ was used as the activator.

Ren X et al. [39] studied experimentally about the properties of GPC from waste concrete. The initial setting time was found to

be varying between 21 to 151 minutes and it was affected by the binder to aggregate ratio as well. It was also seen that the high calcium fly ash-based geopolymer paste/concrete has a shorter initial setting time than the class F fly ash-based geopolymer paste/concrete in general.

Ding Y et al. [41] studied the fracture properties of fly ash/slag based GPC cured in ambient temperature. It was found that the increase in alkali concentration from 3% to 5% increased the compressive strength of slag/fly ash GPC by 83.6%. Increase in slag content also increases the compressive strength due to the presence of calcium. The splitting tensile strength of fly ash/slag based GPC increased by 32.3%, when the alkali concentration increased from 3% to 5%.

Jithendra C et al. [22] studied the role of super plasticizer on GGBFS based GPC under ambient curing. GPC was made up of 100% GGBFS, Na_2SiO_3 to ratio of 2.5, alkaline activator to binder ratio of 0.5, super plasticizer (2% to 6%) and the concentration of 12M NaOH. The workability of concrete was increased with increase in percentage of super plasticizer. It was found that the compressive strength slightly decreased with increase in percentage of super plasticizer.

Chindaprasirt P et al. [9] investigated the basic properties like workability and strength of geopolymer mortar made from coarse lignite high calcium fly ash. The geopolymer was activated with NaOH, Na_2SiO_3 and heat. The results revealed that, increase in NaOH and Na_2SiO_3 concentrations reduced the flow of mortar. The workable flow of geopolymer mortar was in the range of $110 \pm 5\%$ – $135 \pm 5\%$ and was dependent on the ratio by mass of Na_2SiO_3 to NaOH and the concentration of NaOH. The obtained compressive strength was in the range of 10–65 MPa. Improvements in the workability of the mortar could be achieved with addition of water or super plasticizer. However, the use of super plasticizer had an adverse effect on the strength of geopolymer. The optimum Na_2SiO_3 to NaOH ratio to produce high strength geopolymer was 0.67–1.0. The concentration variation of NaOH between 10 M and 20M was found to have a small effect on the strength.

S.K.Saxena et al. [34] investigated the fire resistant properties of geopolymer cement mortars. Fly ash, GGBFS, calcined clay and silica fume were used as the different alumino silicate materials. The alkaline solution was a combination of 8 % NaOH and 10% Na_2SiO_3 . The presence of silica fume increased the development of compressive strength as it increases the geopolymerization and decreases the porosity. Geopolymer mortars made from all the raw materials were quite fire resistant up to 600°C but after that the fire resistant property decreased. Fly ash based geopolymer mortar containing silica fume had the maximum fire resistant property at 800°C and 1000°C.

Saha S et al. [35] studied about the addition of GGBFS to enhance the properties of fly ash based GPC. In this study, GGBFS is added 10%, 20%, 30%, 40% and 50 % of the total binder. NaOH to Na_2SiO_3 ratio is kept as 1.0 and alkali solution to binder as 0.4. It was found that addition of GGBFS reduced the initial and final setting time of GPC. Initial setting time of geopolymer paste was found to be reduced by 73%–94% and final setting time was reduced by 77%–92% with the addition of GGBFS from 10% to 50% in the mixes when compared to the setting time of geopolymer paste mixes without GGBFS. Compressive strength showed an increasing trend when the concentration of NaOH and the percentage of GGBFS were increased.

Bakharev T. [8] studied about the geopolymeric materials prepared using class F fly ash and cured at elevated temperature. Fly ash was mixed with sodium NaOH and Na_2SiO_3 solutions, providing up to 10% Na in mixtures and water/binder ratio of 0.3. The samples did not harden after 1 day curing at room temperature. The sodium % of sodium (Na) in the alkaline solution had significant role in the compressive strength development of GPC. It was found that keeping the geopolymer samples at room temperature and application heat curing increases the strength significantly. It was found that fly ash activated by Na_2SiO_3 with 6 hour heat curing is better than 24 hour curing for the strength development.

Chindaprasirt P et al. [10] investigated the effect of calcium-rich compounds on setting time and compressive strength development of alkali-activated fly ash (FA) pastes. Three calcium rich compounds viz., Portland cement (PC), $\text{Ca}(\text{OH})_2$ and calcium CaO were used as additives to replace FA at the dosages of 5, 10, and 15% by weight basis. NaOH and Na_2SiO_3 solutions were used as alkali activator liquids in all mixtures. Alkali activator liquid/solid binder (FA and calcium-rich compound) ratio of 0.60, Na_2SiO_3 -to- NaOH ratio of 2.0 and curing at ambient temperature (25 °C) were used for all mixes. Test results showed that the setting time and compressive strength of alkali-activated FA depended on the type and content of calcium-rich compound. The incorporation of all three calcium additives resulted in the acceleration of setting time. Alkali-activated FA with $\text{Ca}(\text{OH})_2$ and PC could improve the strength development; however, the use of CaO resulted in the compressive strength reduction. The 28-day compressive strengths of alkali-activated FA with 15% PC and 5%, 10% and 15% CH met the strength requirement for repair material as specified by ASTM standard. The alkali-activated FA with additives can thus be used as an alternative repair binding material.

Phoo-ngernkham T et al. [36] developed a low cost and sustainable repair material made from alkali activated high calcium FA with calcium carbide residue (CCR). It was found that the setting time decreased with both (CCR) replacement and Na_2SiO_3 to NaOH ratio. As the CCR contains around 89.2 % CaO, the heat generated by CaO helped the geopolymerization. The high Na_2SiO_3 -to-NaOH ratio reduced the setting time also. This was because the reactive SiO_2 from Na_2SiO_3 solution reacted with CaO from high calcium FA and CCR. The fast setting of alkali activated mortar is advantageous for repair material. As per ASTM C881/C881M-14 the required initial setting time for repair material must be less than 30 minutes. Up to 30 % increment in CCR replacement with FA, the compressive strength tended to increase. The maximum was 64.6 MPa for 20% where the control mix had 51.8 MPa. The Na_2SiO_3 to NaOH ratio had also an impact on strength increment, the maximum strength showed on when the ratio was 2.0. The 28-day shear bond strength between repair mortar and concrete substrate tended to increase with increasing CCR replacement and Na_2SiO_3 -to-NaOH ratio up to an optimum level. For example, the shear bond strengths for 100FA- $\text{Na}_2\text{SiO}_3/\text{NaOH} = 2.0$ and 80FA/20CCR- $\text{Na}_2\text{SiO}_3/\text{NaOH} = 2.0$ were 9.0 and 15.0 respectively.

Laskar S M et al. [33] studied about the mechanical properties of ultra-fine slag based geopolymer (UGGBS) as a concrete repairing agent. It was found that the GPC mix containing only UGGBS had very poor workability of 25 mm. Addition of FA increases the workability and polyether based super plasticizer efficiently increased the workability. Addition of Fly ash in UGGBS based GPC decreased the compressive strength of the GPC. The mixes without any FA content or low FA content (less than 40%), could attain high strength at early ages. About 50, 80 and 90% of 28 days strength were attained by these mixes at 1, 3 and 7 days respectively. It is evident that the bond strength (pull out) of mix with 30% FA content is highest compared to others.

Huseien G F et al. [20] evaluated the performance of alkali activated mortars containing industrial wastes as a surface repair material. It was found that the increase in FA content reduced the workability (Flow test). The mix containing GBFS and FA in 50:50 ratios exhibited the maximum flow percentage of 56. A steady increment in compressive strength also found with the increased percentage of GGBS in mix. An enhancement in the GBFS content lead to the formulation of the higher amount of C-A-S-H gel in the mixtures containing up to 30% of GBFS than the other mixtures. An increase in the GBFS content could cause the formation of more C-S-H and C-A-S-H gels beside the N-A-S-H gel, which in turn increased the bond strength and improved the microstructures of the GPC mortars especially after the 28 days of age.

Sharkawi A et al. [2] compared geopolymer and high strength grout as repair material for reinforced cement concrete. Two phases of geopolymer mortars have been used; namely plain geopolymer mortar (GPM) and fiber reinforced geopolymer mortar (FRGPM). PP short fibers having 1% volume fraction were used in the FRGPM mix. The results of rebar pull-out test, using geopolymer and grout mortars for anchorage of steel reinforcement should be implemented by surrounding thickness not less than 5 mm. PP fiber reinforced geopolymer repair mortar represents high performance flexural repair material from the ultimate capacity, toughness and crack control points of view.

Koenig A et al. [6] studied the flexural behavior of steel and macro-PP fibre reinforced concretes based on alkali activated binders. The 28 day compressive strength is found to be similar for OPC sample and the Alkali Activated Slag sample. The sample with FA showed the lowest compressive strength even though with the heat curing. The addition of PP fibre and steel fibre had 10% of strength increment in OPC concrete and around 13% decrease for slag based and fly ash based geopolymer sample. No clear trend was found for split tensile strength with addition fibre but the ductility had been improved beyond the maximum load.

Albidah A et al. [1] studied the bond strength between concrete substrate and MK geopolymer repair mortars at ambient and elevated temperatures. Control mortars were cementitious and polymer-modified (PM) mortars. Three plain and three fibres (PVA) reinforced GP mortars were used in this study. The pull of test was conducted according to ASTM 4541-17. The plain and PVA reinforced GP mortars cured at ambient temperature displayed excellent repair potentials in terms of their bond and compressive strengths. The test results indicate that GP mortars are the promising alternative of the cementitious repair mortars.

Ranjbar N et al. [26] studied the mechanisms of interfacial bond in steel and PP fibre reinforced geopolymer composites. As the fibre content increased, a reduction in flow was found both for steel and PP fibre added geopolymer composites. Steel fibre mix was found to be stiffer than the PP fibre mix. Inclusion of 3% steel fibre by volume of binder (Low calcium FA) shows the maximum flexural strength at 7 days and 28 days. Addition of PP fibre had negligible influence on the flexural strength of the composites. Addition of steel fibre up to 3% increased the early development of compressive strength but PP fibre addition had negligible impact on the compressive strength.

Patil et al. [28] investigated the effect of PP fibre on the strength parameters of GPC. The results showed that the compressive

strength, splitting tensile strength and flexural strength of PP fibre reinforced GPC increased with respect to increase in percentage volume of PP fibres from 1.5% of 12mm, 1.5% of 20 mm and 1.5% of hybrid PP fibre. Addition of 1.5% volume fraction of PP fibres of 20mm showed maximum increase in compressive strength, split tensile strength and flexural strength. The effects of volume fraction of PP fibre other than 1.5% on the mechanical properties of GPC were not considered in this study.

Mohseni E [17] assessed the impact of ratio of Na_2SiO_3 to NaOH on the performance of PP fibre -reinforced MK based geopolymer composites. It was seen that compressive strength of samples with Na_2SiO_3 to NaOH ratio 3 has 10 % increment that with that of ratio 2. The specimens with Na_2SiO_3 to NaOH ratios of 2, 2.5 and 3 and 0.3 percent of polypropylene showed flexural strengths of 7.03, 7.51 and 7.69 respectively while 1% PP fibre showed the strengths 9.02, 9.36 and 9.87 respectively. This shows that addition of PP fibres can control cracks and reduce the number of cracks and their width.

Sukontasukkul P et al. [29] studied about the toughness and flexural properties of hybrid steel and PP fibre reinforced geopolymer. The compressive strength of plain geopolymer was 40 MPa. When steel fibres were added in 0.5% and 1%, the compressive strength increased to about 56.6 and 61.7 MPa respectively. For PP fibre, the compressive strength for 0.5% PFRG is found to be higher than that of plain geopolymer. In the case of a hybrid fibre GPC when the base fibre (1.0% polypropylene) is replaced by steel fibre at a 0.2% increment in volume fraction, compressive strength started to increase. The highest strength of this type of hybrid fibre geopolymer is 56.8 MPa with 0.2% polypropylene +0.8% steel fibre. But the compressive strengths of all hybrid GPC samples are lower than that of 1.0% steel fibre GPC. A comparison among the fibre reinforced GPC showed that steel fibre geopolymer has higher flexural strength than the PP fibre reinforced GPC. Regardless of the fibre type, the toughness is found to be increased in increase in percentage of fibre content.

Reed M et al. [30], this research was aimed at investigating the effect of heat curing by comparing the mechanical properties such as compressive strength and ductility of ambient cured and heat cured FRGPC samples. This research investigated the effects of PP fibres in GPC using 0.05 and 0.15 % fibres (by weight). There were two test variables namely the amount of PP fibres used and the curing method/duration. Three levels of PP fibres (0, 0.05 and 0.15 % by weight) and three levels of curing (ambient cured for 24 hours, oven cured for 3 and 6 hours) were investigated. The results reveal that, compressive strength of GPC is not affected by the curing method for low-strength concrete and the majority of the strength of GPC is reached in 21–28 days. Heat curing can speed up the initial strength development. The addition of PP fibres improved the compressive strength from 28MPa to 33MPa and ductility of GPC. Better compressive strength and ductility was found when fibre content was kept at 0.15%.

Zhou J et al. [21] studied about the cement hydration and micro structure in concrete repairs with cementitious repair materials. For unsaturated substrate deceleration in hydration of repair material occurs and reduces the porosity and leads to a dense pore structure. The interface and repair material have high bond strength and tensile strength. When the substrate is saturated water flows from substrate to the repair material, there by increases the hydration in the repair material and leads to a dense structure.

Cabrera J G et al. [23] studied the mechanical properties of different repair materials for concrete structures like OPC, cementitious repair materials (CRM), polymer modified cementitious repair material (PMC) and pulverized fuel ash (PFA). It was found that the CRM showed the highest compressive strength and bond strength and the failure occurred through interphase meaning failure in cohesion.

A.S.E. Belaidi et al. [3] studied the mechanical properties of cementitious repair mortar, silica fume with synthetic fibre and silica fume without fibre. It was found that the silica fume with synthetic fibre shows the highest compressive strength. Flexural strength also showed the same properties. The shrinkage of synthetic fibre added with silica fume showed the least value. The bond strength calculated from the pull out test was more in the case of synthetic fibre added silica fume. It was also noted that water absorption is increased by the addition of fibres.

Feng S et al. [32] compared the microstructure and interfacial bond properties of normal concrete and ultra-high performance concrete repair materials. The compressive strength and split tensile strength of UHPC repair concrete are 127.61 and 13.65 MPa respectively compared to 45.5 MPa of normal concrete (C45). For a given substrate it was found that UHPC materials have more cohesion and shear bond strength.

Banthia N et al. [27] studied the permeability under stress and the bond strength between old concrete with the fibre reinforced cement concrete. The fibres used were cellulose and Poly vinyl alcohol (PVA). It was found that permeability under stress value equal to half of the ultimate strength, less than that of unstressed specimen. Three fibre volume fractions were studied, 0%, 0.5% and 1%. The bond strength increases according to the increment in the fibre content.

Lei F et al. [19] investigated about sustainable phosphate based rapid repairing material and their mix proportions. The raw materials used to make the repair material are circulating fluid bed (CFB) fly ash and Magnesium oxide (MGO)-containing by products and potassium dihydrogen phosphate (KDP (P))- industrial grade white crystalline powder with 98% monopotassium phosphate (KH_2PO_4). The utilization of LG-MgO can reduce the exploitation of natural high-purity MgO.

Litina C et al. [12] developed a sustainable concrete repair material through microencapsulated agents. Five repair mortars from Fosroc Ltd were selected for this project and the self healing microcapsules contained a solution of mineral oil and Na_2SiO_3 (40% weight in water). Three different percentages, 8%, 16% and 32% of microcapsules were selected for the study. The experiments proved the repair materials showed improved crack width and crack depth reduction and permeability improvement.

Stanaszek-Tomal E. [18] investigated about bacterial concrete as a sustainable building material. A self-healing process (Autogenous) takes place with the use of products formed in the presence of carbon monoxide dihydrate and water. Calcium carbonate or hydration products such as C-S-H are formed in order to cause crack healing. Directly introduced magnesium oxide and bentonite can cause the crack healing. Another method, (Autonomous) by the use of bacteria, organic compounds and encapsulated materials with pozzolan. In this treatment, chemical factors such as calcium lactate and biological factors, i.e., bacteria are distinguished. Their coupling enables better end results to be obtained. Recycled concrete aggregate 50% FA as bacterial immobilizers showed the most effective repair of cracks up to 1.1mm wide and allowed to recover the compression strength of 85%.

Micro concrete are repair materials consists of a mixture of graded sand , cement and water to have properties of cement which could be used for small scale works especially repair works. Micro concretes are available in pre packed bags where cement and sand are mixed in dry conditions. Different forms of micro concrete in pre packed bags are available for the patch works or repair of concrete pavements.

In their work, Jonbi j et al. [24] found that addition of PP fibre does not have effect on setting time of micro concrete repair material yet it increases the flexural strength and compressive strength of by 2.9 % .The addition of 1 % of super plasticizer (Polycarboxylate Ether, PCE) increases the compressive strength by 24.3 % after a day. The flexural strength increments are 9.7 % for PP fibre addition and 22.6 % for PP fibre plus PCE addition.

Krishnamurthy R R et al. [31] replaced coarse aggregate and clean river sand (Fine aggregate) with shredded rubber and grinded plastic bottles (Polypropylene, PP) in different percentages in OPC concrete for the repair work. 6mm of shredded tyre and 5 mm grinded plastic bottles were used for the replacement with different percentages which are 10%,20%,30%,40% and 50 % by weight of coarse (12 -14 mm) and fine aggregate. They found that both recycled materials were able to replace either coarse or fine aggregate and the optimum percentage for the maximum indirect split tensile strength was found to be 10 %. Even if the percentage of replacement is 50 %, still the indirect split tensile strength was found to be more than that of the site sample of highest tensile strength.

Guan Y et al. [40] studied about application of Calcium sulfoaluminate cement for the rapid repair of concrete pavement. 70 % of 28 days strength was found to be achieved in a day for these types of cement. The result could make way to open the repaired area for traffic even 4 hrs after repairing. The shrinkage volume change also 38 % less than conventional cement.

Arora A et al. [4] studied about the possibility of using Magnesium phosphate cement as a pavement repair material. The compressive strength increased by 75 % from 1 hr to 1 day curing period when the phosphate magnesium ratio is 1:2. Though the flexural strength was more in the initial 28 days of curing but as the curing period reached 90 days the flexural strength was found to be less than that of OPC .The water resistivity is MPC is not as so great , the strength decreases by 42.34 % for 28 days when it is engrossed in water.

CONCLUSION

The following conclusions were made from the literature review,

- Use of geopolymers with blended binders such as FA and GGBFS, the CO₂ emissions can be reduced by 19-29 % compared to OPC Concrete.
- The type of alkaline solution has a significant influence in the development of compressive strength in GPC Na_2SiO_3 .
- For the blended geopolymer composite materials, the increase in slag content and increase in concentration of alkali solution increases the mechanical properties such as compressive strength and split tensile strength.

- The presence of calcium compound in the binder of GPC reduces the setting time of concrete.
- Addition of super plasticizer in to geopolymers increases the workability of GPC but it has a slightly inverse effect on the compressive strength. Increase from 2% to 6% of super plasticizer increases the workability to 40.7%.
- Geopolymers prepared with high calcium FA has optimum strength when the NaOH to Na₂SiO₃ is from 0.67 to 1.00.
- Geopolymers show good fire resistance up to 6000C, and then the fire resistance compound is getting reduced.
- Addition of GGBFS from 10-50% in to FA based GPC reduces the initial setting time by 73-94% and final setting time by 77-92 %
- Long pre-curing at room temperature is beneficial for strength development of geopolymeric materials utilising fly ash and cured at elevated temperature and if the activator is Na₂SiO₃, 6 hours heat curing is more beneficial than 24 hours curing.
- Alkali activated FA with addition of calcium rich compounds like OPC, CaO or Ca(OH)₂ resulted in accelerated setting time but CaO addition reduced the compressive strength.
- Addition of Calcium carbide residue up to 20 % in the fly ash based GPC increases the shear bond strength of the material. The CaO present in Calcium carbide decreases the setting time of the repair mortar.
- Addition of FA in to UGGBS based geopolymer repair improves the workability of the mix but adding more than 40% of FA reduces the compressive strength. The bond strength is maximum when the FA content was 30%
- GPC concrete containing FA and GGBFS as binders shows better compressive strength and splitting tensile strength as the percentage of GGBFS increases in the binder mix.
- Addition of PP fibre does not have any effect on the fibre reinforced concrete but 1% addition increases the compressive strength by 24.3% after day.
- Addition of PCE based super plasticizer along with PP fibre increases the flexural strength of fibre reinforced concrete by 22.6%
- PP fibre reinforced geopolymer repair mortar represents high performance flexural repair material from the point of view of ultimate capacity, toughness and crack control comparing with to plain geopolymer mortar.
- The PVA fibre reinforced MK based GP mortars cured at ambient temperature display excellent repair potentials in terms of their bond and compressive strengths.
- Addition of fibres (Steel or PP) reduces the flow of the GPC and addition of steel fibre up to 3% by volume of binder gives the maximum flexural strength at 7 days and 28 days
- Addition of 1.5% volume fraction of PP fibres of 20mm in GPC showed maximum increase in compressive strength, split tensile strength and flexural strength.
- Addition of 1% PP fibre by volume of binder and with Na₂SiO₃ to NaOH ratio 3 shows excellent flexural strength properties and crack control in MK based GPC
- Comparison among the fibre reinforced GPC showed that steel fibre reinforced geopolymer has higher flexural strength than the PP fibre reinforced GPC.
- The majority of the strength of GPC is reached in 21–28 days and compressive strength of GPC is not affected by the curing method for low-strength concrete.
- Heat curing can speed up the initial strength development. The addition of PP fibres improved the compressive strength by 18% and the ductility of GPC.
- Among the repair mortars, cementitious repair mortar (CRM) showed the highest compressive strength and bond strength consider other repair materials like PMC, PFA and OPC.
- The compressive strength and split tensile strength of UHPC repair concrete are higher that of normal concrete repair material. For a given substrate it was found that UHPC materials have more cohesion and shear bond strength.
- The permeability of the fibre reinforced concrete repair materials at ultimate stress is less than half of that of unstressed OPC repair materials.

- Use of calcium sulfoaluminate cement proved to be a very good option as a rigid pavement repair material due to its early strength gain and shrinkage properties
- Magnesium phosphate cement has good early strength development but the flexural strength after a 90 days period is less than that of OPC and the water resistivity also not so good to be used a repair material for rigid pavements.
- Replacement of coarse and fine aggregates with shredded tyre and grinded plastic bottles in OPC concrete showed an optimum 10% replacement gives the maximum indirect split tensile strength.

In summary, the paper explores the suitability of FRGPC as a sustainable alternative to repair material in rigid pavements. The paper also provided an overview of the various research performed using FRGPC and GPC for different types of application showing its advanced mechanical properties. It is evident that FRGPC will provide a sustainable solution to not just pavement repair but also in all facets of construction.

Emerging Trends in Affordable Housing – GFRG Technology for Self Reliance and Sustainable Growth

K B Agarwal

Ex GM, ITR Co. Ltd., Bareilly

✉ *uday.hakari@gmail.com*

BACK GROUND

Engineering for 'Self reliance & sustainable growth' denotes new or improvised Engineering with raw material & technology available in India. Adequate shelter for all people is one of the pressing challenges faced by the developing countries. India is currently facing a shortage of about 20 million houses. It is found that up to 30% of the construction cost, including material and labour cost, can be saved by using the new technologies in comparison with the traditional construction methods. In rapidly urbanizing areas land has become a scarce commodity. Many governments aim to improve the situation by investing in infrastructures renewal. For sustainable growth rapid & mass construction will bring improvement in economy in general.

DIFFERENT CONSTRUCTION TECHNOLOGIES

- Conventional Load bearing wall structure.
- RCC Framed structure.
- Precast Technology
- Glass Fiber Reinforced Gypsum Panel Technology (GFRG).
- 3D Technology.

3D Technology in building construction is still in experimental stage. It is new, jazzy and cost-effective. 3D printing is part of a wider technological concept known as 'building printing' that uses 3D printing to develop buildings. As construction is still a conservative process in India, this technology will take long time to take off. Its ability to construct buildings of any shape and size in remarkably less time makes it the future of the construction industry.

GLASS FIBER REINFORCED GYPSUM PANEL TECHNOLOGY

GFRG Panel Technology or rapid wall technology has fast emerged as leading technology of future and is fit for mass scale Affordable Housing. A GFRG Panel is basically Calcined Gypsum plaster, reinforced with glass fibers which when filled with reinforced concrete in an appropriate proportion becomes strong enough to act as a local bearing and shear wall.

GFRG panels made of high quality gypsum plaster reinforced with special glass fibers were first introduced in Australia in 1990. This technology replaced the traditional method of construction where use of blocks and bricks was popular for the structure of a house.

These panels are prefabricated and manufactured at factories and brought to the construction site directly. Once the foundation is laid, these panels are erected on the foundation with the help of cranes. These panels do not need plastering and painting.

GFRG Panel can resist the lateral loads due to earthquakes and wind. Not only the walls, but the roof, floors, sunshades and the boundary walls can be made using GFRG panels. Looking at its success and innumerable advantages, the technology is spreading like wildfire and is being adopted heavily throughout the construction industry.

The typical dimension of a GFRG building panel is 13x3x0.127 m. which weighs around 1.6 tons. It is provided with 4 cavities within 1 meter of the panel.

It is possible to design such buildings up to ten stories in low seismic zones (and to smaller elevation in high seismic zones).

GFRG Panel are originally white in color (due to gypsum) and have a smooth finished surface, they can be whitewashed or painted without cement plastering the walls, therefore, providing some scope of creativity for the client.

PANEL MANUFACTURING

- I. The manufacture of GFRG Panels is done in a semi-automatic plant using the slurry obtained by heating the Calcined Raw Gypsum.

The Calcined Raw Gypsum (plaster) is mixed with water, white cement and certain chemicals like D50 (retarder) and BS94 (water repellent) in a mixer.

Different layers of slurries are then spread over a table and are interspersed with glass fibers cut, spread & imbedded uniformly in to the slurry with help of screech roller. Aluminum plugs (for creating hollow cavities) are also imbedded.

After half hour or so, the aluminum plugs are removed and the panels are sent to a dryer. Panels are dried at temperature of 275 degree centigrade. The wall panels can be cut as per dimensions and requirements of planned building.

- II. Mechanical Properties of panels (nominal values, based on test results): Unit weight 0.433 kN/m², Modulus of elasticity EG 7500 N/mm², Uni-axial compressive strength Puc 160 kN/m (4.77 mPa) (Strength obtained from longitudinal compression / tension tests with ribs extending in the longitudinal direction), Uni-axial tensile strength Tuc 34 – 37 kN/m, Ultimate shear strength, Vuc 21.6 kN/m, Out-of-plane moment capacity, (Rib parallel to span), Muc 2.1 kNm/m, Out-of-plane moment capacity, (Rib perpendicular to span), Muc , perp 0.88 kNm/m, Mohr hardness 1.6 (Out-of-plane), flexural rigidity, EI, (Rib parallel to span) 3.5 x 10¹¹ Nmm² /m, Out-of-plane flexural rigidity EI (Rib perpendicular to span) 1.7x10¹¹Nmm² /m, Coefficient of thermal expansion Cm 12x10⁻⁶mm/mm/o C, Water absorption 1.0% : 1 hr 3.85% : (24 hrs Average water absorption by weight % after certain hours of immersion), Fire resistance : Structural adequacy / integrity / insulation 140/140/140 minutes CSIRO, (Australia/ IS 3809:1979), Sound transmission class (STC) 40 dB ISO 10140-3:2010* * ISO 10140-3:2010,

APPLICATION OF GFRG PANELS

- As a light-weight bearing wall.
- As high-capacity vertical and shear load bearing wall.
- As partition wall.
- As roof slabs / horizontal floor.
- As compound wall / Security wall.
- As pitched roofing.
- As cladding in industrial structures.

METHOD OF CONSTRUCTION WITH GFRG PANELS

The construction process up to the plinth level remains similar as in the conventional method. No special foundation is required for the installation of GFRG Panels.

Concrete belts are built at the plinth area with protruding iron rods which are meant to strengthen the interlocking with the cells of the panel.

GFRG Panels are placed at the appropriate positions using mechanical means, preferably a crane and external supports are provided to maintain the verticality. Necessary cuts for doors, windows, sanitary fittings, vents etc. are made as per the design.

The hollow cavities are filled with concrete and reinforcement as per the requirement to strengthen the panels. Generally, concrete is filled in every third cavity of the panel and the remaining cavities can be filled with waste materials like quarry dust.

Finally, waterproofing treatment is carried out for the roofs and floors of the building.

The basic arrangement of GFRG Panel Building System is as follow:

BUILDING A HOUSE WITH GFRG

IIT Madras has built G+1 House using GFRG technology Panels , timeline goes like this:

❖ **Pre Construction Phase**

1. Excavation & Foundation
2. Waterproofing of Foundation
3. Plinth construction.
4. Concrete Flooring.
5. Starter Bars for Panel Erection.

❖ **Construction Phase**

7. Superstructure - Day 1
8. Water proofing for Joints.
9. Concrete filling in Cavities (Wall panels).
10. Placement of First Floor Slab - Day 8.
11. Instrumentation for Structural Performance.
12. Reinforcement cage for Embedded Beams.
13. Screed Concreting on First Floor slab.
14. GFRG panel for stair case.
15. Erection of panels for First Floor - Day 11.
16. Placement of Panels for Roof slab - Day 15.
17. Slab Reinforcement & Concreting of Roof slab.
18. Filling concrete in GFRG Panels.
19. Water proofing in Toilet area.
20. Strain Gauging for structural performance .
21. Flooring

❖ **Finishing Phase**

22. No need to Plastering and go direct to Painting.
23. Painting.
24. Electrical and Plumbing Works.
25. Sanitary Ware and CP fittings.

G.F - 1 BHK + 2 BHK.

F.F - 1 BHK + 2 BHK.

We need crane to erect the GFRG panels on plinth. G.F + F.F – completed Appox within 40 days.

COST ESTIMATION AND ANALYSIS

In parapet = 265.55 Sq. Mt.
 In stairs = 26.24 Sq. Mt.
 In openings = 341.28 Sq. Mt.
 Total = 6061.72 Sq. Mt.
 Total cost of panels = Rs. 67.89 Lakhs

Table -1: Cost Comparison of GFRG Building with Load Bearing Wall Structure and Framed Structure

Description	Types of Building			Savings/Benefits in GFRG when compared to	
	GFRG building	Load bearing wall Str.	RCC Framed Str.	Load bearing wall Str.	RCC Framed Str.
Dwelling units	16	16	16	-	-
Carpet Area	122.19 SqM	116.02 SqM	119.02 SqM	5.32%	2.66%
Total Build up area	2341.36 sqm	2341.36 sqm	2341.36 sqm	-	-
Excavation	Rs. 74,560	Rs. 83,987	Rs. 95,025	11.22%	21.54%
Steel	Rs. 16,21,540	Rs. 11,91,679	Rs. 21,54,550	-36.07%	24.74%
Cement	Rs. 14,22,490	Rs. 24,46,373	Rs. 33,20,647	41.85%	57.16%
Bricks	-	Rs. 25,33,360	Rs. 15,45,745	-	-
Panels	Rs. 67,89,126	0	0	-	-
Course Aggregate	Rs. 13,47,046	Rs. 13,52,470	Rs. 23,42,706	0.40%	42.50%
Fine Aggregate	Rs. 4,09,045	Rs. 10,52,702	Rs. 12,05,517	61.14%	66.07%
Shuttering cost	Rs. 0	Rs. 4,85,590	Rs. 8,13,477	100%	100%
Labour	Rs. 6,24,271	Rs. 27,71,050	Rs. 28,91,952	77.47%	78.41%
Sub Total	Rs. 1,22,88,078	Rs. 1,19,17,211	Rs. 1,42,74,596	-	-
Miscellaneous	Rs. 13,41,690	Rs. 37,45,862	Rs. 41,68,461	-	-
Total	Rs. 1,36,29,768	Rs. 1,56,63,073	Rs. 1,84,43,057	12.98%	26.10%

(Typical Floor Plan)

Standard size of the panel = 12m x 3m x 0.124 m

Rate of GFRG panels (per square meter) = Rs. 1120

Quantity of panels required for G+3 building

In slab = 2883.41 Sq. Mt.

In walls = 3217.80 Sq. Mt

BENEFITS OF USING GFRG TECHNOLOGY

- I. Economical:- GFRG can save up to 30% of total construction cost.
- II. Rapid construction:- Houses, specially large no. of houses can be built faster than conventional buildings. No beams & columns are needed.
- III. Eco- friendly:- GFRG saves tons of cement & sand reducing carbon foot prints & global warming due to use of eco friendly material. Building industry accounts for 40% of world's carbon foot print.
- IV. Cooler Houses:- GFRG keeps homes cooler up to 4 degree centigrade compared to normal buildings, thus reducing use of ACs.
- V. Fire Resistant:- GFRG can with stand 1000 degree centigrade for 4 hours, giving enough time to residents to escape during fire accident.
- VI. Earthquake Resistant:- Major cities like Delhi, Bombay, Kolkata are in Zone IV. GFRG resist earthquake in buildings up to Zone V.
- VII. Light & Strong: – GFRG is light in weight (43 kg/m²) resulting in less load transfer to foundation. However it is 5 times stronger than conventional building, lasting 80 years life without deterioration (conventional building 50 years).
- VIII. Water resistant:- GFRG repels water, hence deterioration of structure due to water seepage from roof or walls and growth of bacteria & vegetation is saved. There is no water leakage during floods. GFRG floor slabs do not bulge due to water.
- IX. More Carpet area with less Maintenance Cost:- Maintenance cost of GFRG houses is less while carpet area is more as thickness of GFRG panels is only 5 inches.

SHORT COMINGS OF GFRG

Following are disadvantages in the use of GFRG Technology:

1. More space needed for crane movement
2. Complicated design makes it uneconomical for making less houses.
3. Skilled labour needed.
4. GFRG panels should be handled with care in transportation and erection.
5. Need specific machinery for cutting GFRG panels at site.
6. Erection and placing of GFRG panels are a bit difficult & crane is needed.

SELF RELIANCE & SUSTAINABILITY

'Since Gypsum is available in plenty at economical price In India, hence this type of construction is self reliant, economical & is sustainable.

ABSTRACT

Because of the frequency of natural disasters occurring in the Caribbean over the last 20 years, damage has been inflicted on the small island developing states (SIDS) coastal residential buildings in particular. This is in part to do with the apparent low resistance of residential buildings, as compared to public buildings, to the different types of oceanic disasters. Generally only buildings being constructed in the urban areas are regulated because of their close location to the regulatory agencies. As a result of this, the rural residential buildings mainly in the proximity of the coastline of the islands, are being designed, constructed and even renovated in an unregulated manner. These are the ones at risk from possible destruction by natural disasters due to non-building code compliance. This research is therefore based on identifying the main risks that are associated with non compliance of coastal residential building codes via a literature review, and identify the gap for further improvements by comparing the main risks with international standards.

Keywords : Building code; Oceanic natural disasters; Coastal residential buildings; Risk; Non compliance.

INTRODUCTION

Because of the frequency of natural disasters occurring in the Caribbean over the last 20 years, damage has been inflicted on the Caribbean islands coastal residential buildings in particular. This is nothing new to the Caribbean [20]. It is in part to do with the apparent low resistance of residential buildings, as compared to public buildings, to the different disasters. People in Small Island developing States (SIDS) are three times more likely to be displaced by disasters as compared to other disaster zones. One reason for this is that there is no policy in place in the Caribbean to mitigate against this risk. The gap between the Caribbean and other zones is not that wide, as the problem is a global one [1]. The natural disasters outlined in this research are: Earthquakes and Hurricanes relating to oceanic origins.

Regionally, in Barbados it was concluded that construction professionals and Government needs to take more responsibility for building code adherence. It was recommended that adherence to the building code minimum standards be law [2]. Case studies done in Naples and Guadeloupe highlighted technical and institutional capacities should be simultaneously developed. An example of this is developing natural hazards maps for areas and also considering institutional architecture for the area as well [3]. This architecture has to be designed and built by relevant natural disaster compliant building codes. Building codes are essentially provisions for health and safety and structural sufficiency [18].

On an international scale, particularly the United States of America (USA), it was found that due to climate change, more frequent natural disasters are predicted for the future. With this in mind it was deduced that building codes were not as effective in the USA as they could be [4]. Globally, over the past 40 years, approximately USD 40 trillion dollars have been lost due to natural disasters. Natural disasters such as earthquakes and tsunamis account for USD 1.1 trillion [16]. In Mexico there have been failures of mid-rise dwellings because of earthquakes [21]. Bangladesh is, considered by historical data as, one of the most natural disaster affected country in the world. Natural disasters include earthquakes and flooding. Research done on developing a disaster zoning map confirmed that the majority of the county was classed as either high or medium zones [5]. They share coastlines, in part, along the Bay of Bengal with India. The Sendai framework [6] aims to reduce disaster losses in lives, livelihoods, and health adopted in March 2015 in Sendai, Japan by 187 United Nations (UN) member states [19]. This is important as 15 out of the 25 most costly insured global catastrophes has occurred since 2001 to 2011. 80% of these were weather related [17].

RESEARCH FOCUS

The aim of this research is to improve the compliance of coastal building codes.

The objectives are identified as follows:

- To identify and evaluate the existing building code risk inputs for coastal residential building structures regionally.
- To compare these risk inputs to international standards to determine the code compliance gap.

LITERATURE REVIEW

This section addresses the reason for research between residential building codes and coastal natural disasters and identifies the associated risks. Based on the preliminary search, it can be concluded that works have been carried out into this area of research by various organizations. Research organizations considered for this section are:

- Federal Emergency Management Agency (FEMA),
- National Institute of Building Sciences (NIBS), and
- International Building Code (IBC).

The reason for the three organizations is that their research is applicable to the Caribbean Small Island Developing Countries (SIDS). This is because of the geography of the coastlines exposed to coastal natural hazards. We all share relationship with regions above and below the Tropic of Cancer, this is applicable for the Caribbean SIDS, USA in the North Atlantic Ocean and India in the Indian Ocean as well.

Federal Emergency Management Agency (FEMA)

The Recommended Residential Construction for Coastal Areas [7] document by FEMA outlines a number of recommendations and designs for home construction. It was written that while risk cannot be totally eliminated, the intention of the document was to significantly reduce the risk of life and damage to property. These, as also stated can be achieved by designing and building less vulnerable homes.

The document was broken up into a number of sub sections as follows:

Types of Hazards

This section essentially lists and explains the different types of hazards that coastal residential structures are vulnerable to.

- High Winds – This is important as it must be considered when designing as well as building. With respect to hurricanes, the wind speeds are classed into categories as recommended by Saffir -Simpson scale.
- Storm Surge – This is an increase of the sea level by as many as 20-30 feet in some area. It was stated that the surge occurs with a combined force of lower barometric pressure and wind driven waves advancing to the shoreline.
- Flood Effects – This as explained can be as a result of storms and hurricanes. If the surface water has nowhere to drain, it becomes backed up and causes flooding. This coupled with additional water being introduced from the ocean due to storm surge increases the flooding.
- Hydrostatic Forces – Stagnant or very slow moving flood waters cause this effect. It is basically when floodwater forces on opposite sides of a structure are not equal. One result from this is floatation.
- Hydrodynamic Forces – Moving flood waters cause this effect. This moving water can destroy structures as well as move them depending on how much of the structure is submerged and the flow rate of the water.
- Waves – Breaking waves are the ones described as being disastrous. Structures can resist the force from an isolated wave easily, however wave forces are cyclic in nature which results in repetitive force. This is what causes destructions.
- Floodborne Debris – These are produced as a result from the hurricanes and tropical storms.
- Erosion and Scour – This includes the washing away of sand and soils.

These are some of the risks from hazards that can be used in the research.

The Coastal Construction Guide [8] by FEMA also lists out some pertinent risks:

a). Flood Hazards – General Design Considerations

- Erosion.
- Rising sea levels.
- Deposition of sediments.
- Land subsidence.
- Failure of levees.

b). Wind Hazards – General Design Considerations

- Straight line wind- Normally generated by thunderstorms.
- Thunderstorm – These normally move through an area rapidly, generating high winds and heavy rains for a couple minutes on average.
- Downburst – This is a powerful downdraft emanating from a thunderstorm. As the downdraft makes contact with the ground it spreads horizontally, typically 6,000 - 12,000 feet across. Added to this is the vortex ring, typically 2,000 feet above the ground. This generates high winds and heavy rains usually for 15-20 minutes.
- Tornado – These are massive rotating columns of air starting from the base of a thunderstorm to the ground. This can generate winds over 200 mph center.
- Hurricane – These are massive spiraling winds coming together with increasing speeds towards the storm or the eye of the hurricane. They form over warm waters and the diameter of the hurricane can be anywhere from 50 miles to 600 miles. Winds speeds can be over 155 mph as seen in figure 2 above.

c). Other Hazards

- Earthquake and seismic events – These events can cause liquefaction, landslides and tsunamis.
- Tsunamis – These are large waves generated in the ocean and sustained over a long period of time. They can travel great distances in deep water and grow quite large in shallow coastal waters.
- Indoor air quality- Mold grows in the absence of proper air flow in moist areas in the household. A main location is the HVAC systems. After a storm, generally there is usually long term power outages. Therefore the mold would have time to grow.

National Institute of Building Sciences (NIBS)

The Natural Hazards Mitigation Saves Report [9] was geared to considering the benefits of the following economic risks identified:

- Deaths, injuries and post-traumatic stress disorder.
- Property repair costs for buildings and its contents.
- Additional living expenses: sheltering costs for displaced households.
- Direct business interruptions; loss of revenue etc.
- Indirect business interruptions: loss of economic activity etc.
- Loss of service to the community when public buildings are destroyed. E.g. hospitals, fire stations etc.
- Urban search and rescue costs.
- Environmental losses.

These are also some of the risks from hazards that can be used in the research.

International Building Code

This is used as a template to guide a countries' specific code. An example of this is Bangladesh. The country has no official

building code, and relies on a draft code. The draft code[10] provides a comprehensive commentary on the rules for proper residential housing construction. However no relevant code compliance model was proposed for the complete adherence of the code from end users. Overall, in the listing by the Coasts at Risk report [11], Bangladesh ranked as the 7th country most at risk to coastal threats. 29% of the population comprising of 32 million people live in the coastal zone of the country [12]. The coastal zone is entirely in the Bay of Bengal with the length of the coastline being 580 km. Natural hazards include droughts; cyclones; much of the country routinely inundated during the summer monsoon season. Most of the country is situated on deltas of large rivers flowing from the Himalayas: the Ganges unites with the Jamuna (main channel of the Brahmaputra) and later joins the Meghna to eventually empty into the Bay of Bengal [13]. Risks outlined are consistent with those stated above in the FEMA list.

These are also some of the risks from hazards that can be used in the research.

DISCUSSION

Arising from the literature review, the following **Table 1** can be derived.

Table 1. Risk inputs for coastal residential building structures

Risk Considerations	FEMA	NIBS	IBC
High Winds	X	X	X
Storm Surge	X		X
Flood Effects	X		X
Hydrostatic Forces	X		X
Hydrodynamic Forces	X		X
Waves	X	X	X
Erosion And Scour	X		X
Flood Borne Debris	X		X
Hurricanes	X		X
Earthquakes	X		X
Deaths And Injuries		X	
Cost Of Repairs		X	
Environmental Losses		X	
Economic Losses		X	
Cost For Displaced Households		X	

Table 1 illustrates the international risk inputs considered for this research. These are considerations put in place by the international regulatory agencies used in the literature review. Specific to the Caribbean Small Island developing States (SIDS), the standards that are used as base documents are primarily from the usage of I-Codes. They are the IBC, IMC, IPC and IECC. These are managed by the Caribbean Regional Organization for Standards and Quality (CROSQ) (ICC, 2020). Each country also has their local standards and quality agencies. Based on research, the following **Table 2** can be realized.

Table 2. Caribbean countries exposed to coastal risks from natural disasters& their building code regulatory status

Item	Country	Existing Building Code	Legal Status	Regulatory Status
1.00	High Risk			
1.10	Antigua and Barbuda	Yes	No	No
1.20	St Kitts and Nevis	Yes	No	No
1.30	Guyana	Yes	No	No
1.40	Jamaica	Yes	No	No
1.50	Grenada	Yes	No	No

1.60	St. Lucia	Yes	No	No
1.70	St Vincent and the Grenadines	Yes	No	No
2.00	Medium Risk			
2.10	Trinidad and Tobago	Yes	No	No

Trinidad and Tobago by way of a license agreement, have adopted from the ICC A117.1-2009, 2015 IBC, IRC, IMC, IFGC, IPC and IgCC as the basis for the national code mainly for structural requirements. These in conjunction with the TTS 599 [14] for small residential buildings make up the required building code standards. The TTS 599 is regulated by the municipal corporations. The country’s population is 1,389,860 and the coastline is 362 km. The closeness of the country to the South American mainland makes it outside usual path of hurricanes and other tropical storms. Although there is still a medium level of risk. The population on Trinidad is concentrated in the western half of the island, on Tobago it is in the southern half. Trinidad is bordered by the North Atlantic Ocean in the West, South and East. The Caribbean Sea borders the North, East and South coasts of Tobago. With the East coast bordered by the North Atlantic Ocean.

The Guyana standard code of practice for buildings, GCP 9-1:2005 [15], is the only code in the country. This code is ultimately regulated by the Guyana National Bureau of Standards. Guyana’s population is 779,000 with a coastline of 459 km that is bordered by the North Atlantic Ocean on the East. Some of the main natural hazards are flash flood threat during rainy seasons. The population is heavily concentrated in the northeast coast in and around Georgetown, with notable concentrations along the Berbice River to the east; the remainder of the country is sparsely populated.

Grenada’s population is 111,450 with a coastline of 121 km. The country lies on edge of hurricane belt; with the hurricane season lasting from June to November each year. Volcanism is also a threat. Approximately one-third of the population is found in the capital of St. George’s; the island’s population is concentrated along the coast. The island is located between the Caribbean Sea and the Atlantic Ocean.

St Vincent and the Grenadines has a population of 110,210 with a coastline of 84 km. The main natural hazard threat are hurricanes and the La Soufriere volcano on the island of St Vincent is a constant threat. Most of the population is concentrated in and around the capital of Kingstown. The islands are located between the Caribbean Sea and the Atlantic Ocean.

St Lucia’s population is 181,890 with a coastline of 158 km. The main natural hazard threat is hurricanes. Most of the population is found on the periphery of the island, with a larger concentration in the north around the capital of Castries. The island is located between the Caribbean Sea and the North Atlantic Ocean.

St Kitts and Nevis population is 52,440 with a coastline of 135 km. The main natural hazard threat is hurricanes. Population clusters are found in the small towns located on the periphery of both islands. The islands are located between the Caribbean Sea and the North Atlantic Ocean.

Jamaica has adopted the 2009 I-Codes as the basis for their standards. The country has a population of 2,934,860 with a coastline of 1,022 km. The main natural hazard threat is hurricanes. The population density is high throughout, but increases in and around the capital city of Kingston, Montego Bay, and Port Esquivel. The island is surrounded by the Caribbean Sea.

Antigua and Barbuda’s population is 96,290 and the coastline is 153 km. The island of Antigua is home to approximately 97% of the population; nearly the entire population of Barbuda lives in Codrington. Natural hazards include hurricanes and tropical storms (July to October); periodic droughts. The islands are located between the Caribbean Sea and the North Atlantic Ocean.

Similar to the Caribbean countries, a similar table derived from the same source, [11], for international countries is as follows:

Table 3. International countries exposed to coastal risks from natural disasters& their building code regulatory status

Item	Country	Existing Building Code	Legal Status	Regulatory Status	Gap
1.00	Top Tier				
1.10	Bangladesh	No	No	No	Only a draft code exists
1.20	India	Yes	Yes	Yes	Latest edition was in 2016
1.30	Japan	Yes	Yes	Yes	Up to date

1.40	Netherlands	Yes	Yes	Yes	Up to date
1.50	Madagascar	Yes	No	No	Needs to be regulated.
2.00	Middle Tier				
2.10	Brazil	Yes	Yes	Yes	Up to date
2.20	Denmark	Yes	Yes	Yes	Up to date
2.30	United States	Yes	Yes	Yes	All states are based on the International Residential code (IRC).
2.40	Mexico	Yes	Yes	Yes	Not up to date
2.50	China	Yes	Yes	Yes	Up to date
3.00	Bottom Tier				
3.10	Russian Federation	Yes	Yes	Yes	Up to date
3.20	South Africa	Yes	Yes	Yes	Up to date
3.30	Portugal	Yes	Yes	Yes	Up to date
3.40	Ghana	Yes	Yes	Yes	Up to date
3.50	Israel	Yes	Yes	Yes	Up o date

CONCLUSION

While all of the countries analyzed have existing building codes in use, it can be seen that the international countries have a better regulatory process and legal status to ensure better building code compliance. This is something lacking in the Caribbean as a whole.

All of the countries selected are exposed to different levels of coastal risks. However Brazil, Denmark, US, Mexico and China are all exposed to medium risks just like Trinidad and Tobago. What makes Trinidad and Tobago unique in this grouping is the fact that it is the only country here that is an island. Which, theoretically makes the both islands entirely exposed to coastal risks.

The lack of legal and regulatory status regionally makes it impossible to ensure building code compliance. This further justifies the need for a risk compliance model evaluating coastal residential building codes in the Caribbean with respect to natural disasters.

Analysis and Affine Transformation of Skew Slab

M Ravindra

Department of Architecture, Andhra University College of Engineering (A), Andhra University, Visakhapatnam, Andhra Pradesh

✉ *dr.ravindra.mudunury@gmail.com*

ABSTRACT

Generalised equations are derived for reinforced concrete skew slabs for regular and irregular failure patterns using Yield Line Theory. The variation of strength of a skew slab compared to strength of a rectangular slab for different reinforcement details is studied. Orthogonal skew slabs can be transferred to isotropic skew slabs similar to rectangular slabs using affine transformation by modifying the coefficient of orthotropy. The strength of a skew slab is directly proportional to the strength of rectangular slabs at a particular aspect ratio. If the strength of skew slab is known at an aspect ratio, we can find the strength of the skew slab at any aspect ratio at a particular skew angle. In this paper the skew angle is limited to 35° . The strength of the skew slab is increasing with increase in skew angle at any aspect ratio irrespective of the edge condition. The strength of simply supported slab is half the strength of Continuous Slab.

Keywords : Aspect ratio; Affinity theorem; Orthotropic reinforced concrete skew slabs; Orthotropy; Virtual work equations; Yield line theory.

INTRODUCTION

Skew slabs are the requirement of present situation to satisfy the architectural need, optimum utilization of space etc. Also, in order to cater greater speed and more safety of present-day traffic, the modern highways are to be straight as far as possible. This requirement along with obstacles, complex intersections, or mountainous terrain is responsible for provision of increasing number of skew deck slab. Many bridge decks slabs have been built on skew alignment.

Skew slabs are defined as a four-sided slab having equal opposite angles other than 90° . Skew angle is usually measured clockwise from vertical line perpendicular to the support line of the skew slab. The analysis and design of a skew slab is very complicated due to its shape.

The ultimate strength of such slabs may be conveniently determined by using the yield-line theory

The ultimate strength of such slabs may be conveniently determined by using the yield-line theory proposed by Johansen [1, 2]. Many design codes [3–5] recommend Yield-Line theory as one of the possible methods of slab design. Park and Gamble [6] presented in detail the work/research work done on two-way rectangular slabs for uniformly loaded, point load and line loads along with work equations. Limited literature is available on Balcony slabs [7], Trapezoidal slabs [7, 8], Skew slabs [9, 10]. Major work is limited to simply supported (SS) and continuous slab (CS) edge conditions. Rajesh Kumar et al. [10] derived work equations for all the edge conditions separately and presented moment coefficient tables for skew slabs. In this paper generalized virtual work equations are derived for the predicted possible admissible failure yield line patterns (refer **Fig. 1** and **Fig. 2**) which are applicable to all edge conditions.

METHODOLOGY

The generalized virtual work equations for continuous edge (CS) condition of slab are derived for the predicted possible admissible failure yield line patterns using the virtual work method. Let δ be the virtual displacement at E & F (**Fig. 1**), for the considered failure Pattern-1 of a slab. Three unknown dimensions C1, C2, & C3 are necessary to define the yield line propagation completely. To get the equations for other edge conditions of the slab, modification should be carried out in the numerators of the equations of each failure patterns. For Two Adjacent Side Continuous (TAC) slab $I_c = I_d = 0$, or $I_A = I_D = 0$.

In skew concrete slabs the reinforcement may be placed parallel to the edges of the slab, and hence the plate is not orthotropic [11]. Let the reinforcement be placed in the X direction and in the Y direction so that the plate is orthotropic. The bending resistance, of a yield line making an angle θ with the Y-axis is $K'_x m_{ult} \cos^2 \theta + K'_y m_{ult} \sin^2 \theta$ if the yield line is positive

(sagging) and $I_1 m_{ult} \cos^2 \theta + I_2 m_{ult} \sin^2 \theta$ or $I_3 m_{ult} \cos^2 \theta + I_4 m_{ult} \sin^2 \theta$ if the yield line is negative (hogging).

Generalized equations are derived for both the failure patterns considered. A sample derivation is presented for the continuously supported skew slab Yield line pattern-1(Refer Appendix-B).

Fig. 1. Yield line pattern-1

Fig. 2. Yield line pattern-2

Minimization of Virtual Work Equations

The equations of $W_{ult} L_y^2 / m_{ult}$ of the two failure patterns consist of the unknown non dimensional parameters r_1, r_2, r_3 and r_4 which define the positions of the yield lines. A computer program has been developed in FORTRON for various values of the non-dimensional parameters r_1, r_2, r_3 and r_4 within their allowable ranges in order to find the minimum value of $W_{ult} L_y^2 / m_{ult}$ for the yield line failure patterns considered. In this computer program at different aspect ratio and skew angle, θ of the slab the values of r_1, r_2, r_3 and r_4 were varied at increments of 0.01 in order to find the minimum value of $W_{ult} L_y^2 / m_{ult}$ and the failure pattern. Using the above equations, one can develop useful charts basing on orthogonality which may be used either for design or analysis in general.

Affine transformation of a skew slab

‘Affine transformation’ based on theorems VI and VII of Johansen [1] is a technique that transforms an orthogonal slab into that of an equivalent isotropic slab, whose strength is same as that of original orthotropic slab. The transformation of orthotropic slab to that of related isotropic slab is presented with specific examples for different edge conditions. In order to perform the transformation, charts are required and these charts are prepared using isotropic (affine) reinforcement (coefficients), which means that in each direction the reinforcement is same and unity i.e. $K_x^1 = K_y^1 = I_1 = I_2 = I_3 = I_4 = 1.0$. These charts show the minimum value of $W_{ult} L_y^2 / m_{ult}$ versus aspect ratio of slab for various skew angles. A computer program is developed in FORTRAN which gives the least value of $W_{ult} L_y^2 / m_{ult}$ for orthogonal moment coefficients.

According to theorems VI and VI of Johansen [1], any orthogonal slab can be transformed into an equivalent related isotropic slab provided that the ratio of negative to positive moments in the slab is same and unity. When the ratio of negative to positive moment in the orthogonal slab is same and unity, then such a slab can be transformed into an equivalent isotropic slab directly as shown in Fig. 3, which means that the given orthogonal slab solution can be obtained by analysing the isotropic slab with modified dimensions in the X-direction.

When the ratio of negative to positive moment in the orthogonal slab is not unity, then such a slab can be transformed into an equivalent isotropic slab directly as illustrated in Example 2.

In order to transform an orthotropic continuous skew slab to an equivalent isotropic slab in which the ratio of Negative moment to positive moment in both directions is same and unity using the affine theorem, the length of the slab in X – direction should be divided with $\sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}$. The new aspect ratio is calculated and the value of $W_{ult} L_y^2 / m_{ult}$ is read from affine charts (Appendix-C).

Example 1: Transform a Continuous slab 3m X 3m with $K_x' = I_1 = I_3 = 0.25$, $K_y' = I_2 = I_4 = 1.0$, $\theta = 5^\circ$.

For the given data, we get $W_{ult} L_y^2 / m_{ult} = 28.678$ from computer program.

Since $I_1/K_x' = I_2/K_y' = 1.0$, the given orthotropic skew slab is transformed to an equivalent isotropic slab by dividing the length of the slab in X – direction with $\sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}$.

The modified value of $\mu^* = ((\mu \times \cos^2 \theta) + \sin^2 \theta)$

$\mu^*((0.25 \times \cos^2 5^\circ) + \sin^2 5^\circ) = 0.256$. The new aspect ratio is

$$r^* = \frac{L_x}{L_y} = \frac{L_x / \sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}}{L_y} = \frac{r}{\sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}} = \frac{1.0}{\sqrt{0.256}} = 1.977 \text{ and the value of } W_{ult} L_y^2 / m_{ult} \cong 28.67 \text{ (from Chart No.1).}$$

This principle is illustrated in Fig. 3 using the above methodology.

Example 2: Find the strength of continuous skew slab 4.5m X 3m with skew angle 15° if the orthogonal moment coefficients are: $K_x' = I_1 = 0.6$, $K_y' = I_2 = 0.9$.

Solution: For $K_x' = I_1 = 0.6$, $K_y' = I_2 = 0.9$, $\theta = 15^\circ$ and $r = 1.5$, we get $W_{ult} L_y^2 / m_{ult} = 28.94$ from computer program.

Since $I_1/K_x' = I_2/K_y' = 1.0$, the given orthotropic skew slab is transformed to an equivalent isotropic slab by dividing the length of the slab in X – direction with $\sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}$.

The modified value of $\mu^* = ((\mu \times \cos^2 \theta) + \sin^2 \theta) = ((0.667 \times \cos^2 15^\circ) + \sin^2 15^\circ) = 0.689$. The new aspect ratio,

$$r^* = \frac{r}{\sqrt{((\mu \times \cos^2 \theta) + \sin^2 \theta)}} = \frac{1.5}{\sqrt{0.689}} = 1.807 .$$

The new aspect ratio is 1.807 and the value of $W_{ult} L_y^2 / m_{ult} \cong 32.166$ (from Chart No.1). Since $K_y' \neq 1.0$, the value of $W_{ult} L_y^2 / m_{ult}$ obtained from chart should be multiplied by K_y' in order to get the actual value of $W_{ult} L_y^2 / m_{ult}$, i.e. $32.166 \times 0.9 = 28.940$. Few numerical examples are presented in Table 1.

The COS20 PRINCIPLE

If the strength of SLAB is known at an aspect ratio, we can find the strength of the slab at any aspect ratio using the COS20 PRINCIPLE.

The principle of COS²θ states that the product of the difference in strength between two aspect ratios and square of the Cosines is constant for any skew angle.

$$i. e. \left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r_1} - \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r_2} \right] \cos^2 \theta = C, \text{ where } r_1 < r_2. \quad (1)$$

In other words, if the strength of SLAB is known at an aspect ratio, we can find the strength of the slab at any aspect ratio using the COS²θ PRINCIPLE and this principle is illustrated in Example 3 shown below. COS²θ PRINCIPLE is applicable to all edge conditions provided both the positive moment coefficients and negative moment coefficients are equal to each other. The constants given in **Table 2** for different edge conditions are for isotropic moment coefficients. The constants change if the moment coefficients change. In case of CS, OSD, OLD and TAC edge conditions we can find the strength of the slab at other aspect ratios even though the positive moment coefficients change, as we can find the strength of the slabs for these edge conditions using Affine Transformation. First, we can perform affine transformation and find the aspect ratio of the slab at which $K_x^* = K_y^* = 1.0$. Then by using the COS²θ PRINCIPLE we can find the strength of the skew slab (approximately) using the constants given in **Table 2** without using charts.

Table 1. Affine transformation examples for skew slabs

Sl.No.	Slab	Orthogonal Moment Co-efficients	r	θ	μ*	r*	Strength $W_{ult} L_y^2 / m_{ult}$	Actual Strength $W_{ult} L_y^2 / m_{ult}$	Refer Chart No.

Fig. 3. Affine Transformation

Example 3: In Example 2 affine transformation was done and the strength of the slab was found referring charts. The same thing can be done by using the COS2θ PRINCIPLE.

Using expression (1),

$$\left[51.407_{r=1.0} - \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.807} \right] \cos^2 15^\circ = 1.793 \cong 1.8;$$

for $r = 1.8$, $C = 17.929$ for CS (from Table 2).

$$\therefore \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.8} \cong 32.191$$

Since $K'_y \neq 1.0$ and $K'_x = 0.9$, the value of $W_{ult} L_y^2 / m_{ult}$ obtained from the COS²θ PRINCIPLE should be multiplied by K'_y in order to get the actual value of $W_{ult} L_y^2 / m_{ult}$ i.e. $32.191 \times 0.9 = 28.971$, which is approximately equal to the value obtained from Affine Transformation in Example 2.

Table 2 shows the constants using which we can find the strength of a skew slab at any aspect ratio, r , using the strength of the slab at aspect ratio, $r = 1.0$.

Example 4: Find the strength of the Continuous skew slab at aspect ratio 1.5, if the strength of the Continuous skew slab at $r = 1.0$ is 64.0 for skew angle of 30°.

From the principle of COS²θ,

$$\left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.0} - \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.5} \right] \cos^2 \theta = C$$

From Table 2, for CS, Constant, $C = 14.061$.

$$\therefore \left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.0} - \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.5} \right] \cos^2 \theta = 14.061$$

$$\therefore \left[64.00 - \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{r=1.5} \right] \cos^2 30^\circ = 14.061$$

$$\Rightarrow \frac{W_{ult} L_y^2}{m_{ult}} = 45.253 \text{ (Refer Chart no. 1)}$$

Few numerical examples are presented in **Table 3**.

The strength of skew slab is directly proportional to the strength of the rectangular slab at a particular aspect ratio.

$$\text{i.e. } \left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{\theta} \propto \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{\theta=0.0} \right]_r$$

$$\left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{\theta} = \frac{1}{\cos^2 \theta} \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{\theta=0.0} \right]_r \quad (2)$$

Statements I and II are valid if both the positive moment coefficients and negative moment coefficients are equal to each other, i.e. $K_x' = K_y'$, $I_1 = I_2$.

Example 5: The strength of a 2.5m X 1.25m two adjacent side's continuous rectangular slab is 20.605. Find the strength at a skew angle of 15°.

Using expression (2) we can write,

$$\left[\left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{15^\circ} = \frac{1}{\cos^2 15^\circ} \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{\theta=0.0^\circ} \right]_{r=2.0}$$

$$\Rightarrow \left(\frac{W_{ult} L_y^2}{m_{ult}} \right)_{15^\circ} = 22.084 \text{ (Refer Chart 4).}$$

Preparation of Charts

Design charts (Charts1-9) have been prepared for SKEW slabs and are shown in Appendix-C. Charts1-9 are plotted for $W_{ult} L_y^2 / m_{ult}$ versus skew angle, θ for various values of aspect ratio, r and different edge conditions. The skew angle, θ is limited to 35° and is varied in increments of 5°. The aspect ratio, r is taken between 1.0 and 2.0. While preparing the design charts, the least value of $W_{ult} L_y^2 / m_{ult}$ given by the two failure patterns is considered. Using these charts one can directly design or do analysis of a skew slab. These charts are prepared using isotropic (affine) reinforcement (coefficients) (refer Table 4), which means that in each direction the reinforcement is same and unity i.e. $K_x' = K_y' = I_1 = I_2 = I_3 = I_4 = 1.0$ (refer Table 4).

Analysis and Design Problems

Analysis Problem

A continuous skew slab 4.5m X 3.0 m with skew angle of 10° is reinforced with 10 mm diameter bars @163 mm c/c perpendicular to long span and 8 mm diameter bars @ 250 mm c/c perpendicular to short span. Two meshes are used one at top and one at bottom. Thickness of the slab is 120 mm. Concrete grade is M20.

Two meshes are used one at top and one at bottom. Thickness of the slab is 120 mm. Concrete grade is M20.

Solution

According to IS 456:2000[5], $m_{ult} = 0.87 f_y A_{st} z$, where $z = d (1 - (f_y A_{st} / f_{ck} bd))$ (3)

Taking Effective depth of slab in short span direction=100 mm.

Effective depth of slab in long span direction = 90.00 mm.

Area of the steel perpendicular to long span and short span are 481.45 mm² and 201.06 mm² respectively.

The ultimate moments in short and long span directions can be found using expression (3).

Therefore, m_{ult} parallel to long span=6.956 kNm/m,

m_{ult} parallel to short span = 13.908 kNm/m.

For aspect ratio of slab(r) = 4.5/3.0 = 1.5 and taking m_{ult} = 6.956 kN-m/m, the orthogonal coefficients (**Fig 6**) will be $K'_x = I_1 = I_3 = 1.0$ and $K'_y = I_2 = I_4 = 2.0$. With these orthogonal coefficients and for skew angle of 10°, $r = 1.5$; two predicted failure patterns are evaluated by using computer program to find the governing failure pattern and the final results are as follows:

$W_{ult} L_y^2 / m_{ult} = 56.944$, $r_1 = 3.165$, $r_2 = 3.150$, $r_3 = 2.01$ and the failure pattern is 1.

Alternatively, by performing affine transformation, the modified value of r is 2.09 and $W_{ult} L_y^2 / m_{ult} \cong 28.4.4$ from Chart 1.

Since $K'_y = 2.0$, actual value of $W_{ult} L_y^2 / m_{ult} = 2.0 \times 28.4 = 56.8$.

$$W_{ult} = (56.944 \times 6.956) / (3.0^2) = 44.011 \text{ kN/m}^2$$

W_{dt} = (dead load including finishing)

$$W_{dt} = (0.12 \times 25) + 1.0 = 4.0 \text{ kN/m}^2$$

$$W_{ll} = (44.011 - 4.0) = 40.011 \text{ kN/m}^2$$

$$\text{Safe } W_{ll} = 40.011 / 1.5 = 26.674 \text{ kN/m}^2$$

The intensity of safe uniformly distributed live load on the slab is 26.674 kN/m².

Fig. 4(a). Analysis problem

Fig. 4(b). Orthogonal moments

Fig. 4(c): Orthogonal moment coefficients

Fig. 5(a). Design problem

Fig. 5(b). Orthogonal moment coefficients

Design Problem

Design Two adjacent sides continuous skew slab of span 8.0 m X 4.0 m to carry imposed load of 2.5 kN/m². The skew angle of slab is 15° and it is 130 mm thick. Use M20 grade concrete and Fe415 grade steel.

Given: Aspect ratio of slab = $L_x / L_y = 8.0 / 4.0 = 2.0$, skew angle of 15°

Assuming $K'_x = I_1 = 1.0$, $K'_y = I_2 = 1.0$, $r = 2.0$ (refer Fig. 5) and skew angle of 15°, We get $W_{ult} L_y^2 / m_{ult} \cong 22.084$ and failure pattern is 1. (From Chart-4 for skew angle of slab is 15° and $r = 2.0$ we get $W_{ult} L_y^2 / m_{ult} \cong 22.084$).

Overall thickness of slab = 130.0 mm (say)

Dead load of slab = $0.130 \times 25.0 = 3.25 \text{ kN/m}^2$

Dead loads including finishing's = 4.25 kN/m^2

Imposed load = 2.5 kN/m^2 .

Total design ultimate load = $(1.5 \times (4.25 + 2.5)) = 10.125 \text{ kN/m}^2$, i.e. $W_{ult} = 10.125 \text{ kN/m}^2$

$$\therefore m_{ult} = \frac{10.125 \times 4.0^2}{22.084} = 7.336 \text{ kNm/m} \\ \cong 7.34 \text{ kNm/m}$$

The orthogonal moments are

$$K_x' m_{ult} = I_1 m_{ult} = 1.0 \times 7.34 = 7.34 \text{ kN-m/m}$$

$$K_y' m_{ult} = I_2 m_{ult} = 1.0 \times 7.34 = 7.34 \text{ kN-m/m}$$

According to IS 456:2000[5], $m_{ult} = 0.87 f_y A_{st} z$, where $z = d (1 - (f_y A_{st} / f_{ck} bd))$, (3)

Short span reinforcement:

Positive reinforcement 10 dia bars @ 300c/c = 9.88 kN m/m

Negative reinforcement 8 dia bars @ 260c/c = 7.46 kN m/m

Long span reinforcement:

Positive reinforcement 10 dia bars @ 300c/c = 9.88 kN m/m

Negative reinforcement 8 dia bars @ 260c/c = 7.46 kN m/m

Adopt effective depth as 110 mm and overall depth as 130 mm.

CONCLUSIONS

1. The strength of the skew slab is directly proportional to the strength of a rectangular slab at a particular aspect ratio if both the positive moment coefficients and negative moment coefficients are equal to each other.
2. If the strength of SLAB is known at an aspect ratio, we can find the strength of the slab at any aspect ratio using the $\text{COS}^2\theta$ PRINCIPLE for all the edge conditions if both the positive moment coefficients and negative moment coefficients are equal to each other.
3. Strength of Slab can be found by using affine transformation to find the ratio at which the orthogonal moment coefficients are equal to one and find the strength of the slab at that particular aspect ratio using the $\text{COS}^2\theta$ PRINCIPLE without using affine charts at any skew angle.
4. It has been observed that the strength of CS and SS Slabs are same.
5. It has been observed that the strength of OSD, OSC, OLD and OLC Slabs approximately same for lesser skew ($\theta \leq 10^\circ$) angles.
6. The strength of TAC Slab is lesser than other edge conditions irrespective of the aspect ratio and skew angle.
7. Strength of the slab is increasing with increase in skew angle irrespective of the aspect ratio.
8. Strength of the slab is decreasing with increase in aspect ratio irrespective of the skew angle.
9. For TSC both regular and irregular patterns are governing at aspect ratio 1.4 irrespective of the skew angle.
10. The strength of Simply Supported slab is half the strength of Continuous Slab.

APPENDIX-A

Notation:

	Continuous edge
	Simply supported edge
	Positive yield line
	Negative yield line
CS	A slab supported on all sides continuously (restrained)
I_1, I_2, I_3 and I_4	Negative moment coefficients in their corresponding directions
I_A, I_B, I_C and I_D	Total Negative moment coefficients of their corresponding segments
$I_1 m_{ult}$ and $I_3 m_{ult}$	Negative ultimate yield moment per unit length provided by top tension reinforcement bars placed parallel to X-axis.
$I_2 m_{ult}$ and $I_4 m_{ult}$	Negative ultimate yield moment perunit length provided by top tension reinforcement bars placed parallel to Y-axis.
$K_x^1 m_{ult}$	Positive ultimate yield moment per unit length provided by bottom tension bars placed parallel to X-axis
$K_y^1 m_{ult}$	Positive ultimate yield moment per unit length provided by bottom tension bars placed parallel to Y-axis
L_x	Slab dimensions in X direction
L_y	Inclined Slab dimensions
m_{ult}	Ultimate Yield moment per unit length of the slab
OLC	A slab restrained on one long edge and other three sides simply supported
OLD	A slab restrained on three edges and one long side simply supported
OSC	A slab restrained on one short edge and other three sides simply supported

OSD	A slab restrained on three edges and one short side simply supported
r	Aspect ratio of slab defined by L_x/L_y .
r_1, r_2, r_3, r_4	Non dimensional parameters of yield line propagation
SS	A slab simply supported on all sides
TAC	A slab supported on two adjacent sides continuously (restrained)
TLC	A slab restrained on two long edges and other two sides simply supported
TSC	A slab restrained on two short edges and other two sides simply supported
Udl	Uniformly Distributed Load
W_{dl}	Dead load
W_{ll}	Live load
W_{ult}	Ultimate uniformly distributed load per unit area of slab.
θ	Skew angle
μ	Coefficient of orthotropy

ABSTRACT

In the modern construction industries the utilization of cement plays vital role in the production of concrete and hence the needs of cement is crucial in the construction of Civil Engineering structures, such as building, bridge, dam, and road, etc., The cost of cement is enormous, therefore it is difficult to construct the own building by the poor people in the locality. On the other hand, the production of cement is increased in the cement plant due to increasing the demand of cement in the construction field. While manufacturing of cement in dry process produce the emission of CO₂. The range of CO₂ emission is 0.8 to 1.3 tonne per tonne of cement manufacturing. The CO₂ emission might be increase earth temperature and leads to global warming. The global warming is very dangerous to earth, health and plants. The earth climate will be changed due to increasing the global temperature. It will affect the health of human being and plant life. On focusing these issues, it is proposed to carry out this research work to examine the precise way to partial replacement of cement using waste materials, like, Groundnut Shell Ash (GSA), Ground Granulated Blast Furnace Slag (GGBS) and Wool Fibre (WF). The specimens replaced with GSA (8%), GGBS (35%) and WF (0.3%) has better mechanical properties, such as cube compressive strength, cylinder splitting tensile strength and prism flexural strength of concrete.

Keywords : Cement; Groundnut shell ash; Ground granulated blast furnace slag; Wool fibre.

INTRODUCTION

In current scenario, lot of waste materials are disposed, like, groundnut shell, GGBS, fly ash, maize combs, saw dust, rice husk, millet husk, coconut shell etc., and making environmental hazard. Tonnes of waste materials are disposed on the land with minor effective method of waste recycling only. Some of these disposed waste materials are not fully decomposed and thus making the people as illness [1]. The ash which is obtained from groundnut shell, maize combs, saw dust, rice husk, millet husk, coconut shell, GGBS and fly ash have been used as secondary cementing materials. These supplementary materials help to reduce the permeability of concrete by altering their pore structure and thus improve the durability [2]. The groundnut shell is usually used to cook by burning or dumped or left to decay naturally. It will create nuisance to the people and environment, when it is disposed on the field without doing any recycling process [3-4]. Therefore it is proposed to incorporate the by-product agricultural waste of groundnut shell in the form of ash for the partial replacement of OPC for the preparation of concrete to safeguard the land and people from serious environmental hazards and to achieve the economy in the construction industry by minimizing the cost of construction. When the percentage of GSA level is increasing from 8% of the replacement the compressive strength and splitting tensile strength of concrete is decreased for all the age of concrete. The workability of concrete is also decreased while increasing the GSA replacement level for all water cement ratio when compared with control concrete [5].

Hence, it is decided to utilize another one pozzolanic materials obtained from iron industries, that is, Ground Granulated Blast Furnace Slag (GGBS) in order to enhance the strength and workability performance of concrete incorporated with GSA. The GGBS is a by-product obtained from blast-furnace of iron and steel industries [6-7]. It contains large amount of silicates and alumina silicates of calcium. It is a good replacement for OPC because of it consists of important chemical components such as lime, calcium sulphate and alkalis to activate the slag with OPC [8-10]. The replacement level of GGBS is ranges from 20 to 50% at the interval of 5% by weight of OPC in addition with GSA replacement ranges from 6 to 10%. The adopted concrete mix is M20 and water cement ratio is 0.55. The result shows that the compressive strength of concrete cube is increased when the GGBS is blended with GSA and it is suddenly decreased when the GGBS replacement level is more than 35%. But there is no any improvement in the splitting tensile strength and prism flexural strength of concrete when the cement is replaced with GSA and GGBS. Then, it is planned to improve the splitting tensile and flexural strength of concrete by adding fibre. The fibres can

be classified as artificial fibres and natural fibres. Carbon fibre, steel fibre, metallic fibre, boron fibre, polypropylene fibre, glass fibre, etc., are available in the market as artificial fibre and bamboo fibre, banana fibre and wool fibre are available naturally is called as natural fibre [11-12]. The addition of randomly distributed fibres to brittle cement based materials can increase their fracture toughness, ductility and impact resistance [13]. The wool fibres obtained from Scottish sheep has been used in the soil to get the soil matrix. In his research, the untreated and straight wool fibre was used. The amount of wool fibre used is 0.25% to 0.5% by weight of soil. Tests showed that adding alginate increases compression strength from 2.23 to 3.77 N/mm² at 69%. The addition of wool without alginate (maybe due to its hard workability) does not improve performance so much: adding only wool also increases compression strength at 37%, from 2.23 to 3.05. But the addition of both, wool and alginate improves significantly (doubles) ERROL soil resistance up to 4.44 N/mm². Better results were obtained with a lower quantity of wool [14]. Hence, the wool fibre obtained from sheep (WF) from 0.1% to 0.5% is used in this research work in addition with GSA and GGBS to enhance the splitting tensile and flexural strength of concrete.

MATERIALS AND THEIR PROPERTIES

The materials used in the research work are: Ordinary Portland Cement (OPC), Fine Aggregate, Coarse Aggregate, Groundnut Shell Ash (GSA), Ground Granulated Blast Furnace Slag (GGBS), Wool Fibre (WF), and Super plasticizer.

Cement

The properties of cement used are given in the **Table 1**. The cement contains large amount of Oxides of Calcium, Silicon, Aluminium and Iron.

Table 1. Physical properties of cement

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Specific gravity	3.13
2	Standard consistency	31%
3	Fineness	312m ² /kg

Fine Aggregate

The river Sand is a naturally occurring granular material composed of finely divided rock and mineral particles. The size of sand used in this research work is varying from 600μ to 4.75mm. The physical properties of sand used in this research are given in the **Table 2** and tested in accordance with IS: 2386.

Table 2. Physical Properties of Fine Aggregate

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Specific gravity	2.67
2	Fineness modulus	2.9
3	Unit Weight	1558kg/m ³
4	Absorption of water	2.0%

Coarse Aggregate

The Coarse aggregate used is crushed from granite of size varying from 4.75mm to 20mm. The physical properties of crushed stone used in this work are given in the **Table 3** and tested in accordance with IS: 2386.

Table 3. Physical Properties of Coarse Aggregate

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Specific gravity	2.74
2	Unit Weight	1684kg/m ³
3	Absorption of water	0.5%
4	Crushing value	24.24%

Groundnut Shell Ash (GSA)

The groundnut shell is collected from oil manufacturing industries, was then thoroughly cleaned, dried and burned at a temperature of 500°C to 600°C for a period of 4 hours to get the ash. The size of GSA is varying from 10 to 75 μ . The physical properties of GSA are tabulated in the **Table 4**.

Table 4. Physical Properties of GSA

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Size of GSA	10 to 75 μ
2	Specific gravity	1.93
3	Fineness modulus	4.96
4	Unit weight	1090kg/m ³
5	Fineness	329m ² /kg

GGBS

The physical properties of GGBS are tabulated in the **Table 5**.

Table 5. Physical properties of GGBS

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Size of GGBS	10 to 45 μ
2	Specific Gravity	2.75
3	Unit weight	1172kg/m ³
4	Final Setting Time	289 min
5	Fineness	342m ² /kg

Fibre

Wool fibre is the natural hair grown on sheep and is composed of protein substance called as keratin. Wool is composed of carbon, hydrogen, nitrogen and this is the only animal fiber, which contains sulfur in addition. The wool fibers have crimps or curls, which create pockets and give the wool a spongy feel and create insulation for the wearer. The physical properties of wool fibre are tabulated in the **Table 6**.

Table 6. Physical Properties of WF

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Size of the fibre	0.05mm
2	Length of fibre	25 mm
3	Unit weight	350kg/m ³

Superplasticizer

In this investigation, super plasticizer Conplast SP 430, based on sulphonated naphthalene polymers, complies with IS 9103-1999, BS: 5075 part 3 and ASTM C – 494, Type F was used. Commercially available high performance superplasticizing admixture, Conplast SP430, conforming to ASTM C 494 (1992) was used to maintain the slump of the concrete. The properties, supplied by the manufacturer, are given in **Table 7**.

Table 7. Properties of superplasticizer

Sl. No.	Physical Properties of Fine Aggregate	Properties
1	Composition	Sulphonated naphthalene formaldehyde
2	Appearance	Brown liquid

3	Specific gravity	1.20 at 20°C
4	Chloride content (%)	Nil
5	pH value	7.0- 8.0

MIX DESIGN

Mix ratio of concrete

The mix design for concrete (M20) with the water-cement ratio of 0.55 is carried out by adopting IS 10262-2009 and the details of mix design is listed in **Table 8**. A very lesser volume of Super plasticizer at 1% volume on weight of cement has been used to cause good workability. The proportions of fine aggregate, coarse aggregate, and water are fixed constant throughout the research work. The cement is only replaced with GSA and GGBS. Also the WF is used to increase the tensile strength of concrete.

Table 8. Mix ratio of concrete

Sl. No.	Materials	Mix Proportions	
		In weight	In parts
1	Cement	344.68kg	1
2	Fine Aggregate	616.97kg	1.79
3	Coarse Aggregate	1158.12kg	3.36
4	Water	189.57lit	0.55

Mix Proportions

In this research work, totally 12 mixes were casted to predict the cube compressive strength, cylinder splitting tensile strength and prism flexural strength of concrete at the period of 7 days and 28 days of curing by replacing the cement with GSA, GGBS and WF. The specimen prepared without replacement of waste materials is assigned as control specimen (C). The specimens (P1 to P5) prepared by replacing the cement using GSA from 2% to 10%, the specimens (P6 to P8) prepared by replacing the both cement using GSA from 6% to 10% and GGBS from 20% to 50% and the specimens (P9 to P12) prepared by replacing the all the waste materials, such as, cement using GSA from 6% to 10%, GGBS from 20% to 50% and WF from 0.1% to 0.5%. The details of specimens prepared for this study are shown in **Table 9**.

RESULTS AND DISCUSSIONS

Cube Compression Test

A cube moulds made up of cast iron of size, 150 mm × 150 mm × 150 mm were used to prepare the concrete cubes to examine the cube compressive strength of concrete at 7 days and 28 days curing period. Three numbers of concrete cubes were casted for each proportion and tested. A Compression Testing Machine (CTM) of 200tonnes capacity were engaged to evaluate the compression of concrete cube as per IS 516-1959 standard. The cube specimen was kept over the middle of the lower plate of CTM and the compression load was applied on the cube till the specimen was failed. The testing arrangement of compression test of cube specimen is shown in **Figure 1**. The compressive strength can be calculated using the following formula.

Where,

Cube compressive strength = P/A

P = Ultimate compressive load of concrete (kN)

Figure 1. Testing arrangement of compression test of cube specimen

The test results of compressive strength of concrete cube at the age of 7 days and 28 days of curing were shown in **Table 10**. From the test results, it was examined that that the cube compressive strength of concrete for control specimen (C) at the curing age of 7 days and 28 days were 13.63N/mm² and 24.57N/mm² respectively. The cube compressive strength of concrete at the age of 7 days and 28 days was nearly close with the control specimen with a replacement level of 8% of GSA for cement (P4), whereas, it was reduced for other percentage of substitution of GSA (P1, P2, P3 and P5). The cube compressive strength of concrete for all the specimens (P6, P7 and P8) at the age of 7 days and 28 days were higher than that of control specimen, when the cement is replaced with both GSA and GGBS. It was also examined that the cube compressive strength for all the specimens (P9, P10 and P11) at the age of 7 days and 28 days were higher than that of control specimen, when the cement is replaced with

both GSA and GGBS incorporated with WF. The maximum cube compressive strength of concrete is obtained for specimen P10, which is replaced with 8% of GSA, 35% of GGBS and 0.3% of WF. The cube compressive strength of specimen (P10) at 7 days and 28 days of curing were 16.53N/mm² and 26.84N/mm² respectively. The variations of cube compressive strength of concrete specimens are shown in **Figure 2**.

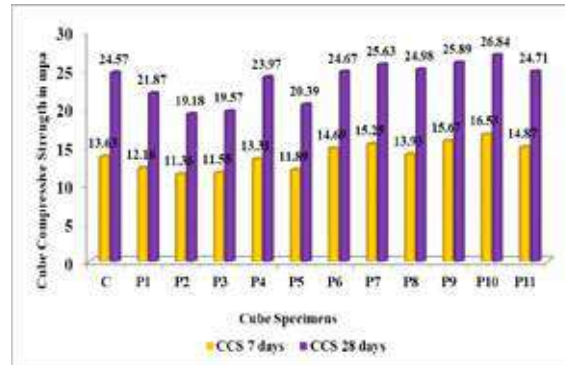

Figure 2. Variations of cube compressive strength

Cylinder splitting tension test

A cylinder moulds of 150mm in diameter and 300mm in height made up of cast iron was engaged to prepare the concrete cylinder to predict the splitting tensile strength of concrete cylinder at 7 days and 28 days curing periods. Three numbers of cylinder specimens were casted for each mix proportion and tested. The concrete cylinder specimens were compressed to evaluate the splitting tensile strength of concrete using Compression Testing Machine (CTM) with a capacity of 200tonnes according to IS 5816-1999 standard. The cylinder specimen was kept over the middle of the lower plate in between the plywood strips and the load was applied on the strip until the specimen was failed. The testing arrangement of splitting tensile strength of cylinder specimen is shown in **Figure 3**. The splitting tensile strength can be calculated using the following formula.

$$\text{Splitting tensile strength} = 2P / \pi DL$$

Where:

- P = Ultimate splitting tensile load in kN
- D = Diameter of the cylinder specimen in mm
- L = Length of the cylinder specimen in mm

Figure 3. Testing arrangement of splitting tensile strength

The test results of splitting tensile strength of concrete cylinder at the age of 7 days and 28 days of curing were shown in **Table 10**. From the test results, it was observed that the cylinder splitting tensile strength for control specimen (C) at the age of 7 days and 28 days were 1.58N/mm² and 2.74N/mm², respectively. It was examined that the cylinder splitting tensile strength at the age of 7 days and 28 days was lower than that of control specimen for the all cylinder specimens partially replaced using GSA for cement (P1 to P5) in various mix proportions. The cylinder splitting tensile strength of concrete specimen (P7) substituted with 8% of GSA and 35% of GGBS at 7 days and 28 days of curing were 1.54N/mm² and 2.73N/mm² respectively. It was understood that the splitting tensile strength of concrete at the curing period of 7 days and 28 days were very near to the control specimen (C) with a replacement level of 8% of GSA and 35% of GGBS (P7). At the same time, it was declined for other specimens replaced with GSA and GGBS (P6 and P8). The cylinder splitting tensile strength of concrete for all the specimens (P9, P10

and P11) at the age of 7 days and 28 days were higher than that of control specimen, when the cement is replaced with both GSA and GGBS incorporated with WF. The maximum splitting tensile strength of concrete is obtained for specimen P10, which is replaced with 8% of GSA, 35% of GGBS and 0.3% of WF. The prism flexural strength of specimen (P10) at 7 days and 28 days of curing were 1.72N/mm² and 2.89N/mm², respectively. The variations of cylinder splitting tensile strength of concrete specimens at the age of 7 and 28 days are shown in **Figure 4**.

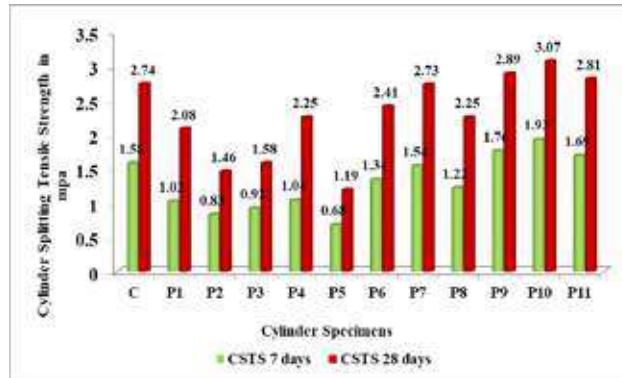

Figure 4. Variations of cylinder splitting tensile strength

Prism Flexural |Test

A prism mould of 150mm × 150mm × 700mm size made up of cast iron was utilized to prepare the concrete prism to determine the prism flexural strength of concrete at 7 days and 28 days curing periods. Three numbers of concrete prisms were casted for each proportion and tested. A Universal Testing Machine (UTM) with a capacity of 60tonnes was engaged to test the concrete prism as per IS 9399-1979 standard. The testing arrangement of prism flexural strength of concrete specimen is shown in **Figure 5**.

The flexural strength of concrete prism of size 15cm × 15cm × 70cm was calculated using the following equation 4.4 and 4.5, Prism Flexural Strength in N/mm²,

$$F_c = \frac{3P_p a}{b_p d_p^2} \text{ (When } a = 20 \text{ cm to } 30 \text{ cm)}$$

$$F_c = \frac{P_p l}{b_p d_p^2} \text{ (When } a = 17 \text{ cm to } 20 \text{ cm)}$$

- Where, P_p = maximum flexural load at failure in N,
- a = distance between the line of fracture and the nearest support in mm,
- b_p = measured breadth of prism in mm at the point of failure,
- d_p = measured depth of prism in mm at the point of failure, and
- l = length of span in mm on which the specimen was supported.

Figure 5. Testing arrangement of prism flexural strength

The test results of flexural strength of concrete prism at the age of 7 days and 28 days of curing were shown in **Table 10**. From the test results, it was noted that the flexural strength of concrete prism for control specimen (C) were 2.14N/mm² and 3.87N/mm², respectively. From the experimental investigation, it was predicted that the prism flexural strength at the age of 7 days and 28 days was lesser than that of control specimen for the all prism specimens partially replaced with GSA for cement (P1 to P5). The prism flexural strength of concrete specimen (P7) substituted with 8% of GSA and 35% of GGBS at 7 days and 28 days of curing were 1.87N/mm² and 3.27N/mm², respectively. It was realized that the prism flexural strength of concrete at the curing period of 7 days and 28 days were somewhat lesser than that of control specimen (C) with a replacement level of 8% of GSA and 35% of GGBS (P7). But, it was abruptly declined for other specimens replaced with GSA and GGBS (P6 and P8). The prism flexural strength of concrete for all the specimens (P9, P10 and P11) at the age of 7 days and 28 days were higher than that of control specimen, when the cement is replaced with both GSA and GGBS incorporated with WF. The maximum prism flexural strength of concrete is obtained for specimen P10, which is replaced with 8% of GSA, 35% of GGBS and 0.3% of WF. The prism flexural strength of specimen (P10) at 7 days and 28 days of curing were 2.56N/mm² and 4.97N/mm², respectively. The variations of flexural strength of concrete prism specimens are shown in **Figure 6**.

Figure 6. Variations of prism flexural strength

CONCLUSION

1. The results obtained in this study signified that when the GSA (From 0% to 10%) alone substituted for the partial replacement of cement, the cube compressive strength of concrete blended with 8% of GSA (P4) at all the 7 days and 28 days curing periods was very nearer to the control specimen (C) and the compressive strength of concrete were decreased for other specimens partially replaced with GSA for cement (P1, P2, P3 and P5) than that of specimens C and P4.
2. On the other hand, the splitting tensile strength of cylinder and flexural strength of prism specimens (P1, P2, P3, P4 and P5) at all the curing periods were declined than that of control specimens. Hence, it is suggested utilize the GGBS (From 20 to 50%) in addition with GSA (From 6 to 10%) for the replacement of cement to enhance the compressive strength of concrete.
3. It was observed that while replacing the cement by 35% of GGBS along with 8% of GSA (P6,P7 and P8), there was an improvement in compressive strength of concrete at all the curing age as compared to control mix. At the same time, the cylinder splitting tensile strength and prism flexural strength of concrete at 7 days and 28 days were reduced than that of control concrete specimen for all the mixes.
4. Subsequently, it is recommended to include a small size (0.05mm diameter and 25mm length) of randomly distributed WF (From 0.1 to 0.5%) in addition with GSA (From 6 to 10%) and GGBS (From 20 to 50%) (P9, P10 and P11) to enhance the cylinder splitting tensile as well as the prism flexural strength of concrete specimens.
5. As a result, it is observed that the specimen (P10) replaced with GSA (8%), GGBS (35%) and WF (0.3%) has better mechanical properties, such as cube compressive strength, cylinder splitting tensile strength and prism flexural strength of concrete.

ABSTRACT

The aim of this research project is the development of a new type of concrete in which integrated bacteria promote self-healing of cracks. Traditional concrete does usually show some self-healing capacity what is due to excess non-hydrated cement particles present in the material matrix. These particles can undergo secondary hydration by crack ingress water resulting in formation of fresh hydration products which can seal or heal smaller cracks. However, the integration of excess cement in concrete is unwanted from both an economical and environmental viewpoint. Cement is expensive and, moreover, its production contributes significantly to global atmospheric CO₂ emissions. In this study we developed a two-component self-healing system which is composed of bacteria which catalyze the metabolic conversion of organic compounds to calcite. Both components are mixed with the fresh cement paste, thus becoming an integral part of the concrete. Experimental results show that ingress water channeled through freshly formed cracks activates present bacteria which through metabolic conversion of organic mineral-precursor compounds produce copious amounts of calcite. This new bio-based two-component system may represent a new class of self-healing mechanisms which can be applied to cement-based systems. The self-healing capacity of this system is currently being quantified what should result in an estimate of the materials durability increase. A self-healing concrete may be beneficial for both economic and environmental reasons. The bacteria based concrete proposed here could substantially reduce maintenance, repair and premature structure degradation what not only saves money but also reduces atmospheric CO₂ emissions considerably as less cement is needed for this type of self-healing concrete. The recent research shows that specific species of bacteria can actually be useful as a tool to repair cracks in early stage of already existing concrete structures. A highly impermeable calcite layer formed over the surface of an already existing concrete layer, due to microbial activities of the bacteria (*Bacillus subtilis*) seals the cracks in the concrete structure and also has excellent resistance to corrosion.

Keywords : Self-Healing; Bacterial concrete; Calcite; *Bacillus subtilis*; Calcium carbonate.

INTRODUCTION

Concrete can be considered as a kind of artificial rocks with the properties similar to that of some kinds of rocks. As it is strong, durable and relatively cheap, concrete is since, almost two centuries, the most used construction materials worldwide, which can easily be recognized as it has changed the physiognomy of rural areas. Normally the concrete as we all know is good in compression but weak in tension. The most of the crack which forms initially is due to tension. Cracks can form at any stage of its life and mostly begin internally where they cannot be seen for years until major repairs are needed. Damage is caused by freeze/thaw cycles, corrosion, extreme loads, chemical attacks and other environmental conditions. Consequently, maintenance to concrete structures is frequent and costly. Billions of dollars are spent every year on buildings, bridges and highways for maintenance, making materials requiring less frequent repairs very appealing. The production of concrete is an energy pensive process when mining, transportation and processing is considered. Its production level lies more than 2.35 billion metric tons per year and contributes an astonishing 10% of CO₂ emissions into the atmosphere. Here the self-healing would enables the fewer repairs works or even failure of a structure through which the production level can even be decreased along with the reduced CO₂ emission.

Tiny cracks on the surface of the concrete make the whole structure vulnerable because water seeps in to the cracks and degrade the concrete and corrode the steel reinforcement, greatly reducing the lifespan of a structure. Repairs can be particularly time consuming and expensive because it is often very difficult to gain access to the structure to make repairs, especially if they are underground or at a great height. High figures of CO₂ emission, energy and materials consumption, structural failures and huge indirect costs are anything but a sign of sustainability. From an environmental viewpoint, the latter concrete types are preferred

as less cement per concrete volume is used contributing to lower CO₂ emissions. Although high strength concrete allows building of more slender structures than ordinary concrete and thus need less concrete volume, the total amount of cement used is still significantly higher due to the inherent high percentage of non- or partially hydrated cement particles in the material matrix. The development of a self-healing mechanism in concrete that is based on a potentially cheaper and more sustainable material than cement could thus be beneficial for both economy and environment. The main goal is to develop a type of self –

BIOMINERALISATION IN SETTING TIME

Healing concrete using a sustainable self-healing agent, i.e. limestone-producing bacteria. Although bacteria, and particularly acid-producing bacteria, have been traditionally considered as harmful organisms for concrete, recent research has shown that specific species such as ureolytic and other bacteria can actually be useful as a tool to repair cracks or clean the surface of concrete. Self-repairing concrete biologically produces calcium carbonate crystals to seal cracks that appear on the surface of the concrete structures. Specific spore forming alkaliphilic bacteria genus *Bacillus*, supplied with a calcium-based nutrient are incorporated in to the concrete suspended in mixing water. These bacteria based self-healing agent is believed to remain hibernated within the concrete for up to 200 years. When cracks appear in a concrete structure and water starts to seep in through, the spores of the bacteria starts microbial activities on contact with the water and oxygen. In the process of precipitating calcite crystals through nitrogen cycle the soluble nutrients are converted to insoluble CaCO₃. The CaCO₃ solidifies on the cracked surface, thereby sealing it up. It mimics the process by which bone fractures in the human body are naturally healed by osteoplastic cells that mineralize to reform the bone. The consumption of oxygen during the metabolic biochemical reactions to form CaCO₃ helps in arresting corrosion of steel because the oxygen is responsible to initiate the process of corrosion thereby increasing the durability of steel reinforced concrete structures.

USING BACTERIA TO SELF-HEAL CRACKS IN CONCRETE

Bacteria added to concrete mix in suspension state must meet certain criteria. Concrete is a highly alkaline building material, so bacteria used as self-healing agent should be able to survive in this high alkaline environment for long durations and be able to form spores (highly resistant structures) withstanding mechanical forces during concrete mixing. In the concrete technology laboratory, a bacterial concrete mix is prepared using alkali-resistant soil bacteria *Bacillus subtilis* along with nutrients from which the bacteria could potentially produce calcite based bio-minerals. It was found that strains of the bacteria genus *Bacillus* were found to thrive in this high-alkaline environment. Such gram positive bacteria have extremely thick outer cell membrane that enables them to remain viable until a suitable environment is available to grow. They would become lively when the cracks form on concrete surface allowing water to ingress into the structure. This phenomenon will reduce the pH of the concrete environment where the bacteria incorporated become activated.

A peptone based broth medium supplied along with bacteria in suspension helps in producing calcite crystals. It is found that this biomineralisation process will not interfere with the setting time of the concrete. The most expensive ingredient in developing bacterial concrete is nutrients. So any inexpensive alternative for laboratory growth media would potentially bring down the cost of the bacteria based self-healing sustainable concrete. Only factor need to be checked is the effect of nutrients media on the setting time of cement. So this needs proper study while using suitable medium.

MECHANISM OF SELF-HEALING USING BACTERIA

The microorganism used for manufacturing of microbial concrete should be able to possess long-term effective crack sealing mechanism during its lifetime serviceability. The principle behind bacterial crack healing mechanism is that the bacteria should be able to transform soluble organic nutrients into insoluble inorganic calcite crystals which seals the cracks. For effective crack healing, both bacteria and nutrients incorporated into concrete should not disturb the integrity of cement sand matrix and also should not negatively affect other important fresh and hardened properties of concrete. Only spore-forming gram positive strain bacteria can survive in high pH environment of concrete sustaining various stresses. It was reported that when bacteria is added directly to the concrete mix in suspension, their life-time is limited due to two reasons; one is continuing cement hydration resulting in reduction of cement sand matrix pore diameter and other is due to insufficient nutrients to precipitate calcite crystals. However, a novel method of protecting the bacterial spores by immobilization before addition to the concrete mixture appeared to substantially prolong their life-time.

BACILLUS SUBTILIS

This strain isolated from soil has characteristics of high level urease activity, incessant precipitation of dense insoluble calcite crystals and has high negative zeta-potential. Potential applications of biological mineral precipitation are wide such as in sand

consolidation and stabilization, remediation of cracks in concrete, preservation and restoration of historic heritage structures, areas where it is not possible to shut down the plant or hazardous for human beings to reach for repair work such as nuclear power plants, repair of waste water sewage pipes etc. These are the most bacteria to use for self-healing purposes since these are alkaliphillic spore forming bacteria. The bacteria, from this genus *Bacillus subtilis* is adopted for present study. The bacteria are cultured in the broth medium of artificial brothextract.

PRINCIPLE OF SELF-HEALING PROCESS

Specially selected types of the genus *Bacillus*, along with a calcium based nutrient and nitrogen and phosphorus in presence of oxygen, the soluble calcium source is converted to insoluble calcium carbonate by ureolytic activity. The calcium carbonate solidifies on the cracked surface, thereby sealing it up. It mimics the process by which bone fractures in the human body are naturally healed by osteoblastic cells that mineralize to reform the bone. MICP occurs via far more complicated processes than chemically induced precipitation. The bacterial cell surface with a variety of ions can non-specifically induce mineral deposition by providing a nucleation site. Ca^{2+} is not likely utilized by microbial metabolic processes; rather it accumulates outside the cell. In medium, it is possible that individual microorganisms produce ammonia as a result of enzymatic urea hydrolysis to create an alkaline micro environment around the cell. The high pH of these localized areas, without an initial increase in pH in the entire medium, commences the growth of $CaCO_3$ crystals around the cell. Possible biochemical reactions (vide Eq. a, b & c) in Urea- $CaCl_2$ medium to precipitate $CaCO_3$ at the cell surface can be summarized as follows

VIABILITY OF BACTERIA IN CONCRETE

Growth of bacteria in concrete is a most questionable factor because of concrete's high alkalinity which is a restricting aspect for the survival of the bacteria. Only specific alkaliphillic bacteria can survive in such hostile environment of concrete. Therefore, it is necessary to immobilize the bacterial cells and to protect them from the high pH in concrete. Polyurethane (PU) has been widely used for immobilization of nutrients and bacterial cells even silica gel was used to protect the bacteria against the high pH in concrete. Several studies show that the bacteria can survive for several hundred years if spores remained unaffected.

MORPHOLOGY OF NATURALLY PRECIPITATED CALCIUM CARBONATE CRYSTALS

$CaCO_3$ is available in three different crystal structures but with same chemical formula in the form of Calcite, aragonite and vaterite. Most stable form of $CaCO_3$, Calcite is rhombohedra in shape. It is formed due to the presence of magnesium, manganese and orthophosphate ions. Aragonite is a orthorhombic shaped crystal form of $CaCO_3$ and geologically changes into calcite over time at high temperature or low temperature in the presence of magnesium ions and pH less than 11. Vaterite mineral is rarely found in nature. It is produced in the pH range from 8.5 to 10, low Ca^{2+} concentration or low temperature and high Ca^{2+} concentration. The morphology of vaterite depends on the pH value and temperature. It was morphology of the crystals does not depend on calcium source only.

The study of M V SeshagiriRao (15) showed that using SEM analysis it was proved that the rhombohedra shape to calcite crystals is due to the presence of chloride ions where as spherical shape to crystals is due to the presence of acetate ions.

EXPERIMENTAL PROGRAM

The main aim of the present experimental program is to obtain the specific details of the crack healing of the concrete incorporated with the bacterial species of specific kind. This experimental program involves

Phase 1: Culture and growth of *Bacillus subtilis*.

Phase 2: Evaluation of the compressive strength of the concrete incorporated with the bacteria.

Phase 3: Healing mechanism of the self-repairing concrete.

MATERIALS USED

Following are the details of the materials used in this investigation:

Cement OPC of 53 grade locally available is used in this investigation. The Cement is tested for various properties as per the IS : 4031 – 1988 and found to be confirming to various specifications of IS: 12269 – 1987 having specific gravity 3.0.

Fine aggregate locally available clean, well graded, natural river sand having fineness modulus of 2.89 conforming IS: 383 – 1970 was used as the fine aggregate.

Coarse Aggregate crushed angular aggregate of size 20 mm nominal size from the local source with specific gravity of 2.7 was used as coarse aggregate.

Water locally available potable water conforming to IS 456 is used.

Microorganisms *Bacillus subtilis*, a model laboratory soil bacterium which is cultured and grown at Biotech Laboratory was used at a total cell concentration of 10⁵ cells per ml by serial dilution.

Mix Design The mix proportion for the ordinary grade concrete and standard grade concrete are designed using IS 10262 – 1982. Materials required for 1 cubic metre of concrete in ordinary grade concrete (M 20) is

Ordinary Grade Concrete (M 20)	Mix proportion 1: 2.43: 3.31: 0.55
--------------------------------	---------------------------------------

RESULTS AND DISCUSSION

The strength characteristics of the standard cubes (100mm x 100mm x 100mm) with and without the bacteria were casted and tested as per the IS code. The several cubes were tested for the compressive strength and remaining for the healing phenomenon analysis i.e. the self-repairing phenomenon by calcite precipitate formation. The standard results of the compressive strength are tabulated in **Table 1**. The increased in the compressive strength in bacteria induced specimen is nearly 19.4% as in **Table 2** than the controlled specimens. For the crack healing study the bacteria induced concrete is allowed to develop the first crack by loading and then the crack healing phenomenon is studied by allowing the ingress water and atmospheric air to pass through the developed crack. The study reveals that the crack is healed to some extent by means of the calcite layer formation, i.e. microbiologically induced calcite precipitation. The **Table 1 & 2** shows the compressive strengths of concrete cube and percentage increase with the days.

Figures depict the comparative results of compression strengths of concrete.

Table 1. Effect of bacillus Subtillus bacteria addition on Compressive strength

Nature of concrete	Compressive Strength of Concrete Cube (MPa)		
	7 days	14 days	28 days
Controlled concrete	14.18	21.61	28.18
Self Healing Concrete	17.01	24.11	32.86

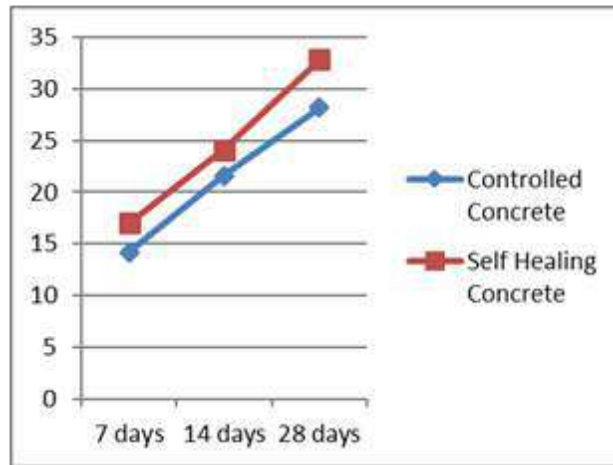

Figure 1. Comparison of compressive strength of Controlled and Self healing concrete

Figure 2. Effect of bacillus Subtillus bacteria on compressive strength

Table 2. Effect of bacillus Subtillus bacteria addition on Compressive strength

% Increase of Compressive Strength of Concrete Cube (MPa)		
7 days	14 days	28 days
19.95 %	11.57 %	16.61 %

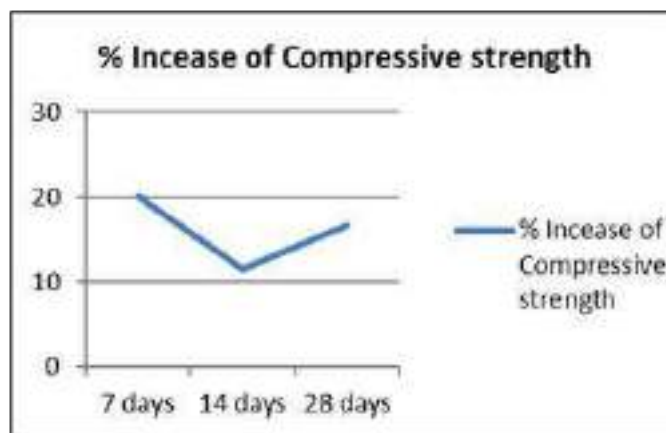

Figure 3. % Increase in Compressive strength of self healing concrete with ages

Figure 4. Crack healed concrete specimen With crack (left) & Healed Specimen (right)

CONCLUSION

Microbial mineral precipitation resulting from metabolic activities of some specific microorganisms in concrete to improve the overall behavior of concrete has become an important area of research. The following are the summary of research outcomes done at the final project

The alkaliphillic aerobic microorganism *Bacillus subtilis* is induced into cement mortar samples at cell concentration of 10⁵ cells per ml in suspension along with the mixing water. The greatest improvement in compressive strength occurs at cell concentrations of 10⁵ cells/ml for all ages.

The study showed that a 16.61 % increase in 28 day compressive strength of cement mortar was achieved. The strength improvement is due to growth of filler material within the pores of the cement–sand matrix. Different cell concentrations were derived from the bacterial growth culture by serial dilution method.

SCOPE OF FUTURE RESEARCH

Bacterial concrete has improved microstructure and permeation properties than controlled concrete. Studies showed that bacterial concrete has better acid resistance in aggressive environments. So, this study can be extended to evaluate the durability performance of the bacterial concrete in terms of acid attack, chloride penetration, porosity, elevated temperature studies and corrosion resistance studies.

ABSTRACT

Energy efficient building to fight against COVID -19 is found a very relevant research work in the development of building technology taking into account energy efficiency, water efficiency, environment protection, indoor air quality and innovation of the building. In the energy efficiency, main focuses are kept on building orientation, building envelope design, HVAC and lighting system design, renewable energy like solar photovoltaic, biofuel, wind power, hydro power etc. , system commissioning, measurement and verification. Water efficiency is done considering design with minimum water usage and efficient irrigation system, rain water harvesting, recycling of water, minimizing water usage in cooling tower. Under the environment protection weightage has been given on the site material like low VOC for the building, proximity of the location to public transport, minimum heat island effect, minimum light pollution, building reused material, usage of material with recycling, usage of rapidly renewable energy material, usage of regional material etc. Indoor air quality in the building is mainly dealt with proper design of ventilation system, controllability of lighting and thermal comfort.

Keywords : Energy efficiency; Building envelope; Renewable energy; Environment protection; Water efficiency.

INTRODUCTION

The COVID-19 pandemic has highlighted the necessity of access to affordable, sustainable energy. Wellness oriented design and development strategies have therefore become the new determinants of market competitiveness and investment appeal, according to sustainable development demands. To contain this pandemic, residents have to remain indoors. Therefore, energy efficient buildings now play a significant role. Community and building-based prevention and control measures namely natural ventilation, indoor disinfection and cleaning, avoiding gathering; waste management, controlling the exhaust backflow of kitchens and bathrooms; setting up effective water seals to reduce the risk of virus transmission through drainage pipes and stools; controlling the concentration of indoor particulate matter; controlling air-conditioning system by zones; well-designed site wind environment for dissipation of viruses and harmful gases; air and water quality monitoring; changing the room function when necessary into medical rooms, transitional residential rooms, isolation and observation rooms, storage rooms, enable energy efficient buildings to contain the virus effectively and provide quick access to medical facilities. Energy efficient buildings using energy efficient building material with anti-bacterial function have been designed to control indoor air pollutants like ammonia, formaldehyde, benzene, total volatile organic compounds, radon, PM2.5 and PM10; moisture condensation on the inner surface of this building to prevent the growth of pathogenic bacteria; prohibiting smoking; ensuring water safety; and having gyms to promote physical movement and thereby boost immunity. Since most of the development is directly linked to energy resources available in a country, every nation ought to pay attention towards creation of new energy sources or towards conservation of energy. So, a large percentage of GDP is actually going towards the energy resources. Around one third of total energy is consumed in building and built environment.

METHODOLOGY OF CONSTRUCTION

One of the major construction materials used in buildings is cement, but its manufacture consumes a lot of energy and leaves a significant carbon footprint. This can be reduced by using RCC, anti-corrosion and anti-cracking concrete. Carefully selecting construction materials ensures lesser impact on environment and optimized recycling of the materials. Accumulation of industrial waste like fly ash, silica fumes, granulated blast furnace slag can be considerably reduced by incorporating them into concrete mixes as cement substitutes. Utilising locally acquired materials can reduce energy consumptions due to transportation. Fly ash has become an important substitute for bricks. Fly ash bricks are cheaper than conventional bricks. Eco-friendly tiles are an improvement on the conventional ones. They are less expensive and consume less energy in their production. For low maintenance, water proof yet washable paint, coloured lime is suitable. For better insulation and improved

cooling, glazed windows maybe used. Argon and krypton may substitute for air, to fill up the cavity between the glass panes. Glazing also provides privacy. Placement of hollow bricks with a gap in between provides insulating effect. Solar heat can be used for generating electricity by installing solar photovoltaic devices. This reduces energy consumption. The system consists of using solar panels containing solar cells which have photovoltaic materials. Rain gardens can not only be used for rain water harvesting for domestic use, but the collected water may also be used to run micro hydro turbines to generate energy. To reflect or absorb solar heat certain finishes and paints can be used. Windows and doors can also be designed in order to reflect heat. All of this in combination reduces cooling load. Solar heat gain coefficient(SHGC) is a ratio that measures the amount of heat passing through all windows of a building to the total heat that actually falls on them. Visible transmittance is a ratio of the visible light that gets transmitted through the glazing. Lower values of SHGC means reduced heat transfer to the building and lower values of VT. A proper balance is required between lighting and heating requirements. Roofs are made cooler by applying reflective coating. An optimum window to wall ratio ensures maximum daylight into the building.

BUILDING ENVELOPE AND ANALYSIS OF RELEVANT BUILDING MATERIALS

Opaque Building Envelope

1) Insulation Materials: The most commonly used insulation materials based on physical characteristics[9] and their respective thermal conductivities(λ)[1] are: mineral fiber blankets and loose-fill products like fiberglass [λ : 0.035 W/(m*K)], rock wool; mixed or poured-in with concrete materials like perlite [λ : 0.04-0.055 W/(m*K)], vermiculite [λ : 0.069-0.071 W/(m*K)], cellulose [λ : 0.04-0.045 W/(m*K)]; foams like polyethylene foam [λ : 0.035-0.05 W/(m*K)], extruded polystyrene(XPS) [λ : 0.03-0.04 W/(m*K)], polyurethane(PUR) [λ : 0.02-0.04 W/(m*K)] etc.

2) Insulation Types: It includes vacuum insulation panels(VIPs) and structurally insulated panels(SIPs). VIPs have excellent thermal efficiency, high performing, with a low thermal conductivity of 0.003W/(m*K) to 0.02 W/(m*K)[9].

3) External Wall: It play a key role in the building envelope and their R-value i.e. their thermal resistance has a significant impact on energy consumed by the building during its life-cycle, especially true in case of buildings having high wall to envelope ratio[9]. A few advanced wall systems are as follows:

- Light Weight Concrete Walls(LWC)-low in their density as well as thermal conductivity and mixed with light weight aggregates to improve their thermal resistance;
- Ventilated walls are walls with air cavities enclosed within two layers and are mainly needed for passive cooling. Increasing air cavity width increases performance but only up to 0.15m. Approximately 40% cooling energy can be conserved during summer[2];
- Walls with latent heat storage use PCM technology(phase change material). Their heat storing capacity is dependent on the percentage weight of PCM material present within the wall. They help decrease the temperature by 4.2K within a room[6]; For wall insulation exterior walls should have high thermal resistance. Materials used should be Fibreglass, Styrofoam etc. to be placed on the inner side and an optimal thickness is required for proper energy conservation.

4) Roofs: The roofs of buildings receive a very high percentage of the solar heat and thus play a key role in the building envelope. Various roof systems are given below:

- Masonry Roofs: These are usually concrete roofs, which absorb tremendous amount of sunlight and heat. An increase in the outside temperature during daytime heats up the roof leading to rising indoor temperature. For such roofs, radiation reflectors and thermal insulation work together as compound roof structures, reduce heat gain during the day.
- Lightweight Roofs: LASRS (lightweight aluminium standing seam roofing systems) have poor thermal characteristics, which can be improved through insulation and coating. The use of light coloured coating along with insulation materials like polyurethane on outer roof surface conserved around 53.8% of peak cooling load compared to a dark coating[4;9].
- Ventilated Roofs: Have ducts placed between slabs to allow free movement of air to conserve the cooling load during summer. This air flowing through the ducts may be natural/passive) or active.
- Vaulted and Domed Roofs: It lowers the indoor temperature considerably during the day in comparison to flat roofs. More energy is released by such roofs at night through thermal radiation and convection, in comparison to flat roofs.
- Solar-Reflective Roofs: Due to high infrared emittance and high solar reflectance(SR) it decreases surface temperature. Solar reflective coatings like aluminium coating can raise the SR value to 0.6 and more.

- Thermal Roof Insulation System: It uses various insulation materials like fibreglass, polystyrene etc. to reduce the high heat gain or the heat lost through the roof. This insulation in combination with a reflective surface can reflect infrared radiation.

Transparent Building Envelope:

1). Windows: Another key part of the building envelope that regulate the movement of air, light and heat to and from the building. The main concern of the modern window systems is to provide a spectrally selective glazing for an improved visible transmittance while maintaining a lower SHGC(Solar Heat Gain Coefficient) and contributing to reduced energy consumption in the building.

- Single Glazing: Windows with tinted glazing absorb more solar radiation than clear windows which gets transformed into heat inside the glass increasing its initial temperature. This however leads to discomfort within short range and a reduction in visible transmittance more so than that of SHGC; Windows with reflective glazing are coated with the likes of metal oxides to improve their reflective properties. They give better room heat gain and SHGC values but a low visible transmittance value; Windows with low-emissivity glazing give improved U-value and SHGC value but lead to rising glass temperatures. However this temperature can be reduced by applying low e-coating to the outer surface, but in turn will lead to rising room heat gain[3].
- Double Glazing: To improve the energy performance of windows it may be doubly or triply glazed, whereby an air or gas filled cavity is enclosed between two glass panes which give low U-values and SHGC values. In comparison to single glazed windows, here the room temperature and inner glass temperature are considerably reduced. This technique limits the presence of condensation in a room and acts like a barrier against moisture.

BUILDING DESIGN CONCEPTS AND BUILDING SYSTEM

The design of a building takes into consideration various conflicting factors like aesthetics, climate, structure, budget etc. The design also has impact on the sources of energy consumed by the building and the unwanted heat trapped inside.

Passive Building Design Guidelines

It envisages the use of the natural environment to meet the heating and cooling demands of the building. The design should be focused on natural ventilation and shading along with appropriate building materials to make efficient use of the natural sun light and air. The key elements of passive building design are:

- 1) Window Sizes and Ventilation: Regulate air circulation as well as insulation and temperature within a room. By increasing the velocity of air within the room in hot climates generates cooler temperature without requiring air- conditioners. The use of low absorption coatings on roofs and other shading devices on the exterior helps maintain optimal temperature. For a higher rate of airflow window sizes with vertical fins are useful. For optimum natural ventilation the aperture arc should be 20% of the entire floor area[10;7].
- 2) Infiltration and Airtightness: Accidental introduction of air within a building through leaks and cracks in the building envelope is known as infiltration, whereas leakage of air to the outside is known as exfiltration. To maintain moisture level, and increase the thermal comfort, while also reducing energy consumption infiltration must be minimized. This increases building efficiency. For this leaks and cracks must be sealed which however may lead to a problem of air-tightness thereby deteriorating the quality of air(International Energy Agency[5]. Studies reveal that buildings in different climates have saved around 5 to 40% energy on heating and cooling by reducing leakage of air[9;5].
- 3) Orientation: The positioning of a building according to the direction of winds and seasonal variations of the sun's rays is an important aspect of passive building design in tropical climates. The orientation should allow maximum air flow while restricting direct sunlight. Windows and vents should be on opposite walls for optimum air circulation. Some vents should be located at the top of building for expelling the rising hot air on the inside. The longer side of the building should be aligned along north and south with width to length ratio of 1:1.7, to reduce heat gains and prevent conflict between solar and wind alignment.
- 4) Daylighting: To combat rising climate change concerns, we must cut down on energy consumption. We may reduce electricity consumption by utilizing sunlight for all insulation and lighting needs. A combination of artificial lighting with natural light can efficiently meet all the requirements. To reduce the use of electric lighting, windows with high shading coefficients glazing along with a high VT is the best[8]; also maximum savings on electricity consumed by lighting is possible by using clear glazing, electrochromic, and finally tinted and reflective glazing[8].

5) Shading and Micro-Climate Modification: Shading devices reduce heat gains, need for air-conditioners, glare problems etc. It also improves thermal insulation and comfort within both ventilated and non-ventilated buildings, though it reduces natural light. Shading can be provided by natural landscaping or overhangs, etc. Though increasing the length of the shading devices reduces cooling load, the heating load is increased. Energy consumption in warmer climates may thereby be reduced. Reducing the energy consumption of the building is another option - micro-climate modifications using plant, trees which provide better shading, and water bodies. Evaporation from a nearby pool helps lower temperature during summer and the high heat capacity of water helps maintain constant temperatures during winter. Introducing a green roof may help reduce the surrounding temperature and the heat within the building, since roofs absorb a lot of heat, though the introduction of vegetation reduces heat flow from the roof into the building. Energy consumption of the building is thus reduced and so is the need for cooling devices.

6) Thermal Mass: The correct usage of thermal mass reduce the temperatures within the room by averaging out the day and night extremes. Building elements like roof, floors, walls absorb heat during the day and release it when the temperature falls, reducing the need for using cooling /insulation devices. In tropical areas, the difference between day and night temperatures is negligible and thus light weight construction materials are more suitable. For effective use of thermal mass proper shading devices should be used in combination with glazing faces in the proper direction.

BUILDING HVAC SYSTEM AND ENERGY CONSUMPTION

HVAC systems of buildings are responsible for at least half the energy consumed in buildings. So, it is necessary to analyse the energy consumed and find ways to reduce the consumption without compromising on the comfort of the residents. Air-conditioning, heating and ventilation constitute the HVAC system. In tropical climates however the major energy consumers are air conditioning and ventilation.

Air-Conditioning, Cooling and Dehumidification

In tropical climates cooling and dehumidification is an important factor. Compression cooling is one such way. The common methods of cooling include single-split or multi-split air conditioners. Some newer technologies include thermal, district and PV- driven cooling. The widely used electricity driven air-conditioner is the single-split. The energy efficiency ratio of air-conditioners must be high for better efficiency and more energy savings. Multiple splits are used in larger homes to reduce cost and space required for installation. Different temperatures can be achieved in different rooms. The PV system generates the electricity and stores it in a battery storage for future use. Thermal driven coolers can save more energy because it utilises the solar heat stored by the system for running the cooling system.

Ventilation

Indoor air quality is crucial for the well-being of the occupants of the building. An efficient ventilation system helps to filter the air supply and expel unwanted heated up air outside. Ventilation system can affect its occupants as follows:

- 1) Hygrothermal comfort: The temperature of the air inside, the relative humidity and air velocity should be homogenous.
- 2) Indoor air quality: To maintain the indoor air quality the inlets and outlets should be far away from each other to prevent intermingling of fresh and stale air.
- 3) Acoustics: Noise from the ventilation system should be kept to a minimum.

CONCLUSION

Design and construction of energy efficient buildings have always been a priority of the building sector but with the alarming climatic changes and a worldwide pandemic, has highlighted the need for creating social awareness about the growing need of designing and constructing green and energy efficient buildings and their benefits. Hereafter buildings will need to take into consideration the obstacles as well as the opportunities brought about by technological, environmental and various societal and architectural changes. This is where smart buildings which have automated systems that can adapt and communicate with its occupants will gain prominence. The construction industry must recognize and incorporate them into their designs and practices. A few of the green technologies that must be incorporated are photovoltaic systems or solar panels to reduce consumption of electricity and fuel which can save around 40% of the load. Use of skylights can reduce requirement of artificial lighting. Low flow fixtures and sensors can reduce water wastage. Rain water harvesting can help store and use of water for domestic purposes including running mini hydro turbines for generating energy. Appropriate ventilation and glazing will reduce

energy consumed for insulation and air-conditioning. Reuse and recycling of construction wastes and incorporating waste as construction components will reduce landfill accumulation. Natural landscaping and planting of trees and other flora will contribute to a sustainable living environment. Smart buildings can therefore bring down energy consumption by at least 40% in comparison to normal buildings.

ABSTRACT

The present evaluation focuses on optimal utilization of GGBS on M50 grade of concrete with various proportions mixes (0%, 10%, 20%, 30%, 40%) and replacement of RoboSand as fine aggregate which was maintained at 30% constant, along with addition of 1% of steel fibre by volume of concrete. For this various cubes, prisms, cylinders were casted and tested for different ages (3, 7, 28 days). To assess the mechanical properties of concrete some test were performed. Mix-3 emerges as the optimal replacement with enhanced value of compressive, split and flexural strength. Addition of steel fibre demonstrates the enhancement of flexural and split properties. Further, Acid attack test was conducted to assess the durability characteristic for optimal mix.

Keywords : GGBS; RoboSand; Steel fibre; Mechanical properties; Durability test (Acid Attack).

INTRODUCTION

Concrete is an ingredient material used in the construction industry it consists of chemically inert particulate substances like as an aggregate (fine aggregate and coarse aggregate) which is bonded with a cement and portable water. As per WHO concrete is a second broadest material consumption by human resources after food and water. The concrete is prepared by the proper mixing of cement, fine aggregate, coarse aggregate and water as per the mix proportions. Later the mix is allowed to cure and finally it is hardened like as stone. The hardening process is takes place just because of present chemical activities between water and cement for this concrete became strong with age. The concrete strength, durability, and many other properties are mainly dependence on the properties of the concrete ingredients, mix proportions, type of method of compaction and many other controls at the time of mixing, compaction, placing, and transportation and at the end curing at the end. Minimum of two proportions of an elevation amount as much compared to the standard materials. GGBS is a by-product material which is obtained from a steel manufacture industry which may be a replaceable material partially with the cement because

of it reduces the ecologically burden with associating with the concrete at both stages like the hardened state and fresh state of the concrete. RoboSand have be proposed for an alternate material for the river sand as it gives an additional strength and profit to concrete and also improves strength in concrete. RoboSand is well-known to enlarge the

potency of concrete. More over it may concrete through up of with a one and the same quantity of river sand. The strength of RoboSand concrete attention ally continues in raise with era for every proportion of RoboSand content in concrete. The proper use of a RoboSand as a fine aggregate it may twirl this desecrate matter. This cause discarding difficulty in nature into a more precious resources the perfect using of RoboSand may reduce the stain problem of supply of natural Fine aggregate and in turns helps cost reduction of concrete.

OBJECTIVES

1. To find out the optimum percentage of GGBS replacement to cement in high strength concrete.
2. To assess concrete's compressive strength with a various proportions of GGBS(10%,20%,30%,40%) to the cement, with the fine aggregate is partially replaced with RoboSand as maintain 30% constant and addition of steel fibre it is also maintain 1% constant by weight of volume of concrete.
3. To assess the concrete's Flexural strength and the Split tensile strength having various proportions of GGBS with constant

materials RoboSand and Steel Fibres.

4. To investigate durability characteristics of GGBS content concrete using HCL solution.

LITERATURE REVIEW

1. M. Adams Joe et.al [1] This current paper focus on investigation of features of M40 grade concrete of with a range of proportional for GGBS with cement and addition of 1% of steel fibre. Maintain water cement ratio 0.35. In the present work GGBS is varied in 0%, 10%, 20%, 30%, 40% & 50% and 1% steel fibre is used for getting the better results. At the end of experimental work it is concluded that 40% replacement of GGBS with cement & 1% of steel fibre are help to increase the force of concrete compare to standard design mix concrete.

2. S.P.Sangeetha et.al [2] For the determination of flexural performance of reinforced concrete beams the cement is replaced by GGBS. This experimental work mainly focuses on flexural force of beam. In this work M30 grade of concrete were used. For cement replacement GGBS are used in the proportion of 0%, 30%, 40%, 50%, 60% tested for 56 days also considering 28 days. Finally this experimental study explains that 40% of GGBS can be a replacement for cement which will be used for reinforced concrete beams. The strength increases about 21% at 56 days as compared to 28 days.

3. B Vidivelli et.al [3] Has investigated the mechanical & durability characteristics of concrete with GGBS & steel fibre for this grade maintained as M30. In this work maintain the GGBS as 20% & steel fibre about 1% the tests are conducted of for specimen 98, 56 & 28 days of all compressive, flexural force & 28 days test for elastic modulus. Along with this work simultaneously we have carried out the durability tests of sulphate attack, acid attack and water absorption. At the end of this experimental investigation we have concluded that GGBS with 20% replacement & 1% steel fibre addition gives better compressive, flexural & elastic modulus of concrete results of about 47.58, 4.5, 32.18 of about 90 days curing and also sulphate attack, acid attack are tested for about weight loss in respect to 7.94 & 10.45 and water absorption test results are 13.56 of about 20 % of GGBS replaced with cement & 1 % of steel fibre addition.

4. Suchita Hirde et.al [4] Through the present experimental work is to determine the mechanical properties of GGBS with adding up of steel fiber. For this GGBS is replaced with cement in the proportion of 0%, 10%, 20%, 30%, 40% by mass of cement and steel fiber are kept unvarying 1.5 % the specimens are cured for 28 & 56 days tested under compression & flexural strength along this flexural toughness indices are also determined. Finally the experimental investigation conclude that 20 % replacement of GGBS which maintains 1.5% steel fiber gives good results of compressive strength. This work is mainly concentrated by varying the GGBS content is varied in size of aggregate of about 10mm, 20mm, 12mm which results of about 61.09 MPa, 61.91 MPa, and 61.01 MPa. Along with this 20mm aggregate with 20% replacement of GGBS gives better flexural results of about 10.26% compare to other size of aggregate.

5. G. Balamurugan et.al [5] In this work variations are considered in the grade of concrete M20& M35. For this the RoboSand is replaced with natural sand. In the proportions of 0% to 100% of about 7 days and 28 days curing. But the test results give a clear image of about RoboSand. In this work finally concluded that 50% replacement of RoboSand material can be replaced to natural sand gives better results of strength achieve in nature beyond this decreases in strength.

6. S.Azhagarsamy et.al [6] The work is to find out the high performance concrete strength by using RoboSand material as replacement material for sand. For considering M60 grade concrete the RoboSand is replaced to natural sand directly i.e. maintained constant & steel fiber are varied in the percentage of 0.5%, 1%, & 1.5% the test were conducted 3, 7, 28 days . Finally the work is concluded that 60% of RoboSand and 1% of steel fiber gives better comfortable results of high performance concrete.

7. R.Rasika Priya et.al [7] In this work the normal sand is replace by RoboSand in this the variations of 10%, 20%, 30%, 40%, 50% & 60%with maintaining 1% of steel powder. At the end of experimental work conclude that 40% of RoboSand With 1% of steel powder gives an optimum strength.

8. Santosh Kumar Karri et.al [8] In this prescribed work explain the GGBS is partially replaced to cement for the grade of concrete M20 and M40 in the range of 30%, 40%, 50%.cubes, cylinders, prisms are casted for determining the compressive, tensile and flexural force of concrete along this durability tests are also conducted like acid tests sulphuric acid and hydrochloric acid used to conduct the work. This experiment finally concluded that for both M20 and M40 grade concrete the GGBS material can be replace of cement up to 40% optimum results for all strengths. In durability properties comparing the H2SO4 with HCL. The compressive strength value GGBS concrete effect of HCL more compare to H2SO4.

MATERIALS

Cement

In this present investigation we use OPC (ordinary Portland cement) as a binding material.

The test results are tabulated in a below table.

Table 1. Shows the Preliminary Test Results of Cement

Particulars of cement	Normal consistency	Specific gravity	Fineness	Initial setting time	Final setting time
Test out comes	33%	3.14	5%	44 min	398 min

Fine Aggregate

In this present project work fine aggregate used is naturally available river sand which is under zone-II as per IS 383:1970. The preliminary experimental outcomes of FA are as shown in the below table.

Table 2. Shows the Preliminary Test of Fine Aggregate

Particulars of FA	Specific gravity	Water absorption	Fineness modulus	Silt content
Test out comes	2.66	1.4%	3.42	2.32%

Coarse Aggregate

In this present project work crushed angular stone size is about 10mm and 20mm were used. Table below shows the properties of Coarse aggregate.

Table 3. Shows The Preliminary Test Results of CA

Particulars of CA	Specific gravity	Water absorption	Fineness modulus
Test out comes	2.73	1.1%	2.24

Ground Granulated Blast Furnace Slag

The slag is a through invention material from iron manufacturing industry. It is mainly composed of 30% to 40% of silicon di-oxide (SiO₂) and also 40% Cao which is also similar as the chemical composition of cement. The GGBS as a replacing material for cement it says that the compressive strength can be high as much as possible. It gives a good workability, durability characteristics in nature and also a cost effective construction material. Test results are shown in **Table 4.**

Figure 1. Shows sample of GGBS

Table 4. Shows the Test Results of GGBS

Particulars	Specific gravity	Fineness (Kg/m ²)	45 Micron (Residue) %
Test out comes	2.88	382	7.40

RoboSand:

RoboSand is used for the present investigation work it is partial replacement material for fine aggregate which was collected from stone brick manufacture in khammam dist. Telangana. The test results are shows in below Table below.

Table 5. Shows the Preliminary Test Results of RoboSand

S.No	Particular	Test results
1	Specific gravity	2.57
2	Fineness modulus	3.10

Figure 2. Shows sample of RoboSand

Steel Fibres

In this experiment to enhance the tensile strength of concrete we are going to add the steel fibre. The steel fibres are hooked at end it is of 1mm diameter and Aspect ratio 50mm. The steel fibres were collected from Maruthi steel suppliers, Bangalore. **Fig 3** shows steel fibres sample and **Table 4** shows the property of Hooked End SF.

Fig. 3. Shows sample of steel fibres

Table 6. Properties of Steel Fibres Used

Properties of SF	Length	Diameter	Aspect ratio	Specific gravity	Tensile strength	Density
Approved values	50mm	1.0 mm	50	7.80	1200 MPa	7860 Kg/m3

Chemical Admixture

Fosroc auramix 300-plus is used as a chemical admixture and its specific gravity is about 1.06.

Potable Water

In this experimental work water is used for concrete mixing and curing. water used as clean, clear & free from acid content and portable water used which is referred from IS - 456 2000 are used.

MIX DESIGN BY ABSOLUTE VOLUME METHOD:

According to IS: 10262-2009 mix design was done for the purpose of concrete casting of various mixes with the help all above preliminary investigation test outcomes. The mix design was done for M50 grade. From the mix design conventional trial mix was prepared and it having mix ratio is 1:2.38:3.10 and the w/c of 0.40.

Table 7. Mix Proportions of Concrete

Material	Quantity (Kg/m ³)	Proportion
Cement	342	1
FA	816.12	2.38
CA	1061	3.10
Water	131.42	0.40
Chemical admixture	4.5	1.2%

EXPERIMENTAL PROGRAM

In this present experimental investigation involves casting of 45 cylinders, 45 cubes and 45 prisms and testing is conducted after curing period of 3,7,28 & 90 days to assess compressive strength, split-tensile strength & flexural-strength of casted concrete. In this work there are five mix proportions to study the variation of strength and to conclude with optimum percentage of the GGBS. The below table VIII represents the different mix proportion details and their percentage. To determine the durability characteristics of concrete, 3 conventional cubes and 3 cubes having an optimum percentage of GGBS, ROBO SAND and Steel fibres are casted.

Table 8. Shows Mix Proportions were Involved in this Present Work

Mix	Cement (%)	GGBS (%)	ROBO SAND (%)	Steel fibre (%)
Nominal mix	100	-	-	-
Mix - 1	90	10	30	1
Mix - 2	80	20	30	1
Mix - 3	70	30	30	1
Mix - 4	60	40	30	1

PROCEDURE FOR CONCRETE CASTING

As per design mix the material are weighed and mixed in tray by hand mixing. The water cement ratio is maintained for this work is 0.40. The specimens are will be casted uniformly distributed & randomly the specimen used trowel with in one hand & in other hand is will be taken by the concrete which it helps to fill the concrete in the specimen. Conventional concrete is casted without any replacement for the purpose of comparing the strength. To get high strength in concrete the variations are made of the GGBS material. With the help of the tamping rod the concrete is tamped in the specimen with 3 layers the casting will be done by hand mixing method. The cylinders & prisms are casted same as that of the cube casting. After casting the specimen is kept it for 24 hours after this the specimen are de molded & kept it in curing tank. Maintain normal temperature the specimens are kept in curing tank for the purpose of curing to getting the high strength. The specimen are keeping it for 3, 7, 28 days respectively. After 3, 7, 28 days curing the testing process are conducted on specimen and note down the all the readings and calculations are done for determination of compressive, split, flexural strength as per our Indian force values.

Fig. 4. Shows freshly casted specimens

Fig 5. Shows the casted Cured specimens

RESULTS AND DISCUSSIONS

Slump Cone |Test

In the fresh state of concrete the test is conducted is slump test for the purpose of checking of the workability of concrete with many trials are conducted. The slump test shows the workability which may increase by rising in proportion partially replaced of GGBS in OPC.

Fig. 6. Shows Slump cone test

Table 9. Represents Slump Test Results

S.No	% of GGBS added	Slump value in mm
1	0%	45
2	10%	58
3	20%	63
4	20%	68
5	40%	59

Compaction Factor Test

For the determination of fresh concrete workability compaction factor test also conducted.

Fig. 7. Shows compaction factor test

Table 10. Represents Compaction Factor Test Results

S.No	% of GGBS added	Slump value in mm
1	0%	0.91
2	10%	0.95
3	20%	0.96
4	20%	0.97
5	40%	0.92

Compressive Strength

From the below Graph and table, we can said that there will be a considerable increase in strength of replacement concrete compare to the conventional concrete. Mix 3 i.e., GGBS 30%, RoboSand 30% and 1% of Steel fibre shows the superior strength compare to other mix.

Table 11. Shows the Compressive-Strength Results

Mix	Compressive strength in N/mm ²			
	3 days	7 days	28 days	90 days
Nominal mix	23.4	37.86	57.86	60.85
Mix - 1	23.95	30.96	43.62	62.78
Mix - 2	24.12	33.47	55.18	64.65
Mix - 3	26.45	37.92	59.96	65.78
Mix - 4	28.54	36.29	53.69	68.39

Fig. 8. Shows the Compressive-Strength results

Split-tensile Strength

From the below graph and table we can say that there is a great influence of presence of chemical admixtures, Mix 3 i.e., GGBS 30%, RoboSand 30% and 1% of Steel fibre shows the better split tensile strength of concrete compare to other mix.

Table 12. Shows the Split-Tensile Strength Results

Mix	Split-Tensile Strength in N/mm ²			
	3 days	7 days	28 days	90 days
Nominal mix	2.26	3.54	4.33	4.99
Mix - 1	2.8	2.68	3.95	4.54
Mix - 2	2.26	2.99	4.29	4.65
Mix - 3	3.13	3.62	4.95	5.03
Mix - 4	3.03	3.44	4.71	4.99

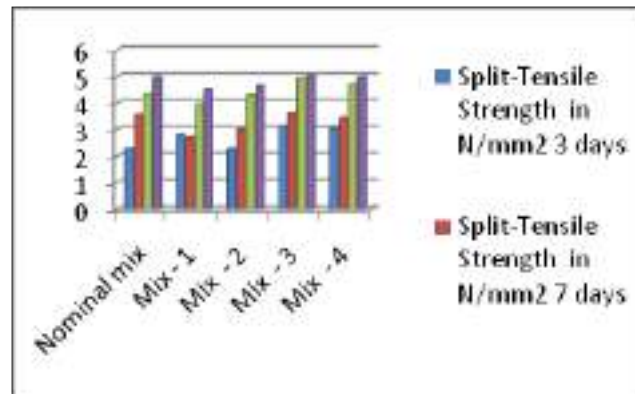

Fig. 9. Shows the Split-Tensile Strength results

Flexural Strength

The flexural prism having size is about 700mm×150mm×150mm were casted and tested under two point load testing machine to assess the flexural-strength. The results show that, the integration of SF shows the good ductility to flexural force. The Mix 3 i.e., GGBS 30%, RoboSand 30% and 1% of Steel fibre shows the extraordinary flexural strength of concrete compare to other mix.

Table 13. Shows the Flexural-Strength Test Results

Mix	Flexural-Strength in N/mm ²			
	3 days	7 days	28 days	90 days
Nominal mix	3.96	5.62	6.03	6.54
Mix - 1	4.36	6.16	6.51	6.87
Mix - 2	4.83	6.13	7.16	7.25
Mix - 3	5.86	7.23	7.43	7.58
Mix - 4	5.06	6.23	6.33	6.98

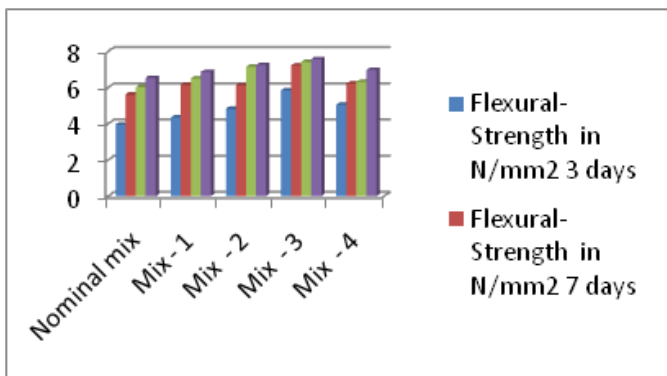

Figure 10. Shows the Flexural Strength results

Acid Test

- To check the durability characteristics of concrete we considered the optimum mix3 i.e. GGBS 30%, RoboSand 30% and 1% of Steel fibre. The cubes were casted and immersed in 5% concentrated hydro choric acid [HCL] solution for 28 days to examine the weight loss in concrete which shows the resistance of concrete against the acid attack environment.
- The resistance to acid for the Mix3 integrated concrete was superior to the CC. From the HCL solution water was absorbed by cubes and forms black whitish film appears on the concrete surface.

- The below Table represents the results for the weight loss in percentage. The presence of GGBS in concrete improves the resistance against the acid attack.
- The average percentage loss in weight was 3.40% whereas GGBS, ROBOSAND and steel fiber content concrete i.e. MIX3 was 1.15%.

Table 13. Shows the weight loss in cubes during due to acid effect

S.No	Mix	Weight of cubes after 28 days	Weight of cubes before 90 days	% of weight loss in cubes	Average weight loss
1	Nominal mix	8.76	8.40	4.1	3.4
		8.77	8.46	3.5	
		8.76	8.53	2.6	
2	Optimum mix (mix -3)	9.45	9.16	3.0	1.18
		9.36	9.12	0.24	
		9.43	9.21	0.23	

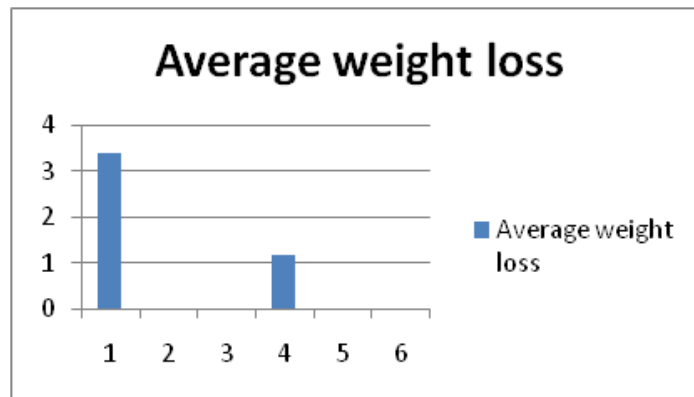

Figure 11. Represents average %age weight loss

CONCLUSIONS

- The workability is to be improved markedly by fresh concrete up to 30% replacement of GGBS to cement above this percentage workability decreases.
- The Compressive Strength increases with the use of GGBS material as replaceable material for cement. The maximum strength achieved in concrete having 30% GGBS, 30% ROBOSAND and 1% SF i.e., Mix 3.the strength increased 2.1% as compare to CC.
- The adding up of steel fibers also improves the split tensile strength of concrete. The maximum strength achieved in concrete having 30% GGBS, 30% ROBOSAND and 1% SF i.e., Mix 3.the strength increased 0.65% as compare to normal concrete.
- The Flexural-Strength also shows the enhancing in strength of concrete with the presence of GGBS, The maximum strength achieved in concrete having 30% GGBS, 30% ROBOSAND and 1% SF i.e., Mix 3.the strength increased 1.4% as compare to normal concrete.
- Hence for the above experimental investigation has concluded that cement with GGBS, sand with RoboSand for 30% partial replacement with addition of steel fiber gives a optimum good results of forces and also helps in improving the strength & durability properties of high strength concrete
- The % of weight loss in GGBS is less as compared to normal concrete i.e. MIX3 (30% GGBS, 30% ROBOSAND, 1% SF) the average weight loss in CC is about 3.4% and in Mix3 the average weight loss is 1.154%.

Effective Quality Management for Sustainable Roads

Kishor Kumar Pahuja

Superintending Engineer UP PWD

✉ *pahujakishore1@gmail.com*

ABSTRACT

Construction industry in India accounts for about 10% of GDP of the country. Out of this the share of roads and highways which form an important part of infrastructure is about 30%. The journey of road development has been a long one. Now we are in an age which facilitates fast moving vehicles reducing travel time and to sustain high and heavier volumes. For sustainability roads are to be built with good quality. Good quality gives consistency in performance and induces reliability giving rise to increase in the confidence level of the system. It is very important for the highway engineers to develop a self-sustaining and reliable system of construction methodology which can integrate quality management to produce sustainable road network. Construction industry and more particularly the projects in the highway sector are of varied nature and require a large number of parameters to be controlled and the end product is produced in a rather open and relatively uncontrolled environment. This gives rise to a big challenge to produce an acceptable quality product. IRC has put in place codes and manuals to guide the requirements in this field. To stay in competition consistent improvement in quality is essential. It is felt that there need to look at and deal with the issue of quality in a comprehensive way and to introduce the concept, ethos and practice of Total Quality Management to get sustainable road system and self-reliance.

Keywords : Words: Sustainability; Consistency; Reliable system; Total Quality Management; Self-reliance.

INTRODUCTION

A good and efficient network of roads is a pre requisite for development and very important element affecting the quality of life of the people. In a country like India with a very large population, road projects constitute a large part of Government investments be it for the improvement of National Highways, Expressways or other category of roads. All road projects have three essential elements. They are scope, time and cost. Scope is decided based on the requirement or the mandate given for the improvement of the existing facility. Scope is something which cannot be squeezed unilaterally by the construction agency. On the other hand there is always a tendency by the contracting agency to reduce the cost they have to incur and at the same time the agency wants to reduce the time as well. Schematically the three elements form three sides of the triangle as shown in **Fig 1**. In addition to these there is an element of quality which is delicately balanced. Hence quality is central to the scheme of things and should maintain its place and should not suffer.

Fig 1. Relation of Quality with Scope, Cost & Time in a Project

Our Prime Minister has recently given a very ambitious call for “AtmaNirbhar Bharat”. This can only be achieved by producing good quality roads which can sustain through their design lifecycle. If the domestic contracting agencies excel in the quality work then they can truly capture larger share in the major projects to bring out a change towards self-reliance as shown in **Fig 2**.

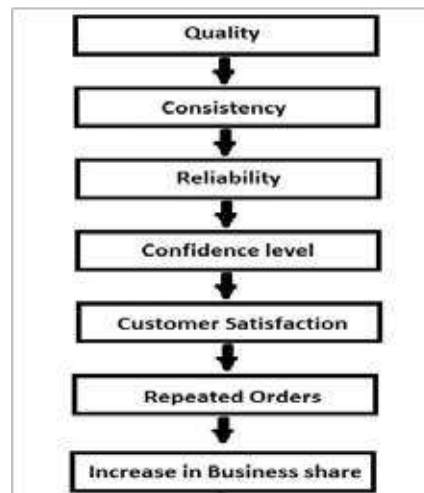

Fig 2. Quality-Consistency Flow Chart

OBJECTIVES OF THE STUDY

- This study has been done mainly to understand issue of quality and to explore potential to improve it.
- To understand the effect and role of quality in the highway sector in the fast developing infrastructure scenario.
- To understand how quality issue is handled in the projects with the guiding principles laid down MoRTH and IRC.
- To see if quality can be continuously improved using concepts like Total Quality Management.

METHODOLOGY

The methodology adopted in this study is through literature survey of the work done in the area of quality improvement in the construction and highway sector. Specifications for Road and Bridge Works by MoRTH and the Manual for Quality Control in Road and Bridge Works IRC:SP 112-2017 has been compared with the practices of Total Quality Management and current practices in Human Resource Management.

CONCEPTS AND DEFINITION OF QUALITY

The word quality has come up from the latin word “qualis” which means “what kind of” . Here the word what kind of has got inherent in it “how good”. Although quality has been defined by many experts but the general sense in which it is used in the organizations is that good quality is that which is acceptable among the customers. So the quality is relative. It is also good as well as bad in different cases. Juran has defined the quality as “the fitness for use therefore quality products should meet or exceed customer requirements”. Crosby has defined quality as “quality is conformance to requirement. Thus requirement must be clearly stated so that these cannot be misunderstood”. Whenever there is mention of quality the two attributes which are quite inseparable from it are consistency and reliability. This implies that the acceptable work or product should not deviate from the acceptable level and it should have high reliability of achieving the standards. High reliability factor means high degree of confidence

PROVISIONS FOR QUALITY IN IRC CODE AND MANUALS

Codal provisions for quality existed before the year 1998 through the MorTH detailed specifications for roads and bridges and the Manual for Quality Control 1984. But after 1998 with the construction of 4 laning of Golden Quadrilateral and expressway construction there was a need to inculcate quality right from planning to construction to operation and maintenance. Thus quality assumed greater importance so that the constructed roads could serve throughout their design life cycle giving safe and comfortable riding facility reducing vehicular operating cost and travel time. Thus the IRC codes namely IRC SP:11-1984 Handbook for Quality Control for Construction of Roads and Runways, IRC SP:57-2000 Guidelines for Quality Systems for Road Construction and IRC SP:47-1998 Guidelines for Quality Systems for Road and Bridges were merged to form IRC SP:112-2017 Manual for Quality Construction in Road and Bridge Works. This manual is an extensive and detailed document listing guidelines from the preparation of road project and through the post construction maintenance. Now this manual in

conjunction with MoRTH Specification for Roads and Bridges is the basis for guiding and controlling the quality of works. Further Guidelines and standard operating procedures for quality control/Assurance in construction of National Highways and other centrally sponsored projects have been issued vide order RW/NH-34066/01/2020-QCZ Dated 01.10.2020. In line with the importance given to the quality by BS 7580-1:1992, Transport Research Board, American Society for Quality Control and American Society for Testing and Materials (ASTM-E699) Total Quality Management has been adopted and various road works have been divided into classes as shown in **Table 1**.

Table 1. Class Nomenclature and QA (Source: IRC SP 112-2017)

Classes of Quality Assurance	Class Nomenclature	Road Classes/Categories Covered
Nominal QA	Q1	Rural Roads in Remote areas
Normal QA	Q2	Rural Roads average size/MDR
High QA	Q3	National Highways& State Highways, Coastal Roads, Roads in High altitude, Roads in high rainfall areas & Large size Projects on Major District Roads
Extra High QA	Q4	Tunnels, Elevated Highways

Though the construction of roads is taken up through various modes like Build Operate and Transfer (BOT), Engineering Procured Contract (EPC), Hybrid Annuity Mode (HAM) in addition to the conventional contract systems the contractor is primarily responsible for construction of quality but role of other stakeholders like engineer and the client is also important. The contractor has to ensure quality assurance plans incorporating organizational duties, responsibilities, procedure, inspection, tests frequencies, acceptance criteria, internal audit etc. The contractor has to get the approval of the Authority or independent engineer for the executed work. The desired quality can only be achieved by adequate and appropriate quality personnel deployed by the contractor at the project. The deployment of personnel required depends on the size of the project as shown in **Table 2**.

Table 2. QC of Personnel of Contractor (Source: IRC SP 112-2017)

Size of Project	Details of Key & Sub Professional
<Rs 300 Crore	Material Engineer-1, QC/ Assistant QC Engineer-2, Lab Technician-4
≤ Rs 300 Crore	Material Engineer-1, QC/ Assistant QC Engineer-3, Lab Technician-6

The duties of personnel shown in **Table 2** are listed in the manual. Similarly for the control and check of quality created by contractor number and duties of personnel to be available with the engineer are also detailed as shown in **Table 3**.

Table 3. QC Personnel of Engineer (Source: IRC SP 112-2017)

Size of Project	Details of Key & Sub Professional
<Rs 300 Crore	Material Engineer-1, QC/ Assistant QC Engineer-1, Lab Technician-2
≤ Rs 300 Crore	Material Engineer-1, QC/ Assistant QC Engineer-2, Lab Technician-4

As per guidelines laid down by IRC SP 112-2017 all materials and finished items and levels etc. have to be checked with the stipulated frequency at all stages of the work. The establishment of laboratory for material testing is a necessary pre-requisite in projects.

As already discussed in section 4 about the concept of quality, it is always the end user, customer or the client whose requirement has to be met with. It is not the builder who is going to use the facility. Builder and user thus stand on the two opposite sides so quality aspect has to be pushed by the user. Also quality just can not be subjective only. Quality has to be evaluated on “measurable” basis. Statistical analysis for assessment of quality is necessary since variability is a reality in road construction. Variability occurs in materials and processes and at different stages in road construction. Under such circumstances statistical analysis helps in taking informed decisions about acceptance. Physical quantities that are expected to be the sum of many independent processes often have distributions that are nearly normal. Normal distribution curve is flatter if variation of data is more from mean and vice versa as shown in **Fig 3**.

Fig 3. Normal Distribution

A With large Dispersion from mean

B With small Dispersion from mean

Depending upon the confidence limits set out for the specific works individual upper or lower specification limits are set, called USL and LSL. There can be single specification limit talking any one of these or taking double limits. Generally different items in road works are specified for 90% confidence level meaning thereby that out of every 100 in the selected lot 90 values will come under the specified limits and 10 values can be accepted to be out of these limits.

QUALITY CONTROL AT DIFFERENT LEVELS

A multi-layer approach is adopted in the case of highway projects. The basic and the first layer is at the level of the contractor where the quality is controlled at the execution level. This is either “in process” or the ongoing controls and can also be “after process” checks when the item gets completed. The second layer of checks is at the level of the engineer or the supervision consultant. There may be higher level inspections from the client side. The third layer is the independent “third party” checks. There may be post construction checks or audits.

Despite these mechanisms to ensure quality the most important level is at the initial first level itself. It is at the level of the contractor that the importance of quality and its role in the building up of the reputation of the firm and the long term advantage has to be stressed. It is with this perspective that total quality planning, organizing; staffing etc. has to be undertaken.

TOTAL QUALITY MANAGEMENT

The Concept Of TQM

Total Quality Management has been adopted in the manufacturing sector. It was developed in post war Japan under the aegis of William Edwards Deming. It has been successfully used in our country also. To achieve self reliance in the field of highway sector companies have to adopt high standards of quality so that they can face the tough competition within the country as well as outside to edge out competitors and win contracts. For this they have to adopt Total Quality Management and approaches like “Six Sigma”. Total Quality Management is different from quality assurance or quality control. In fact TQM encompasses both quality assurance and quality control and is more comprehensive. TQM starts at the planning and project preparation stage. It goes through the implementation and execution and operation phase. There are continuous checks and controls, different tools and management techniques are deployed. The process is refined and the focus is on continuous improvement and to achieve practically “zero defects” output. Some of the features of TQM are:

- It involves everyone in the organization in producing products and services to match the customer’s needs and expectations.
- It is not fixed but a dynamic process involving effectiveness and efficiency of all elements of a business.
- It uses set of tools and techniques and process output which yields customer satisfaction.
- It also integrates functions and processes within the organization to achieve continuous improvement of quality of goods and services.
- Teamwork is practiced.
- Formal system of education and training is adopted.
- Suppliers and customers are integrated into the involvement process.

Three Levels of Total Quality Management:

This is done at all the 3 management stages-Strategic, Tactical and Operational. Fig 4 shows how broad policy, procedure and execution are related to different levels. Policy dictates how the construction company deals with the strategic long term goals and how project work progress is managed which includes the level of importance given to quality. Depending upon the policy initiative, the procedures are formed at the middle level and the requirement about staffing is managed. At the execution stage endeavour is make best use of the personnel and other resources.

Fig 4. 3 Levels vs Policy/Procedure & Execution

Fig 5. Shows how Quality Models, standards and tools are related to different levels.

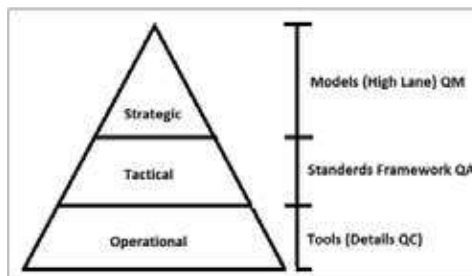

Fig 5. Models, Standards & Tools for QM

Generally the planning a and control activities are related to strategic, tactical and operational level as shown in **Fig 6.**

Fig 6. Strategic/Tactical & Operational level vs Planning & Control Activities

Fig 7. shows a generalized model of organization chart from Strategic perspective which can be adapted. This model integrates needs of the customers and focuses on the continuous improvement principle to achieve quality.

Fig 7. Model of Organization from Strategic Perspective

Human Asset Management approach to Quality

Human Asset Management is the key to achieve quality and to move towards the goal of Total Quality Management. Though the input of machinery has increased in construction yet the controlling of machine output and quality depends on the expertise and intent of the human factor controlling it hence the role of human resource management continues to be important and has become even more comprehensive in the form of Human Asset Management. Some of the important points to be considered are:

- Right number of personnel deployment.
- Appropriate personnel deployment at the appropriate place.
- Exchange of ideas and sharing of information for continuous control and assessment of work quality.
- Retention of expert personnel.
- Continuous Training and up gradation required.
- Keeping the team motivated to achieve best quality.
- Improving group dynamics to achieve larger goal.
- Introducing concepts like Quality Circle in large projects.

Tools and Techniques for Quality Management:

- Cause and Effect Diagram. Any process when analysed in parts by breaking down can reveal major causes of a particular problem.
- Flow Charts show all steps and stages in a process and help in identifying problem.
- Check Lists make checks systematic.
- Control Charts as “in process” controls to check whether a process is statistical control.
- Scatter Diagrams show relationship of two variables.
- Pare to Charts to identify causes and prioritize solution.
- Histograms showing graphical representation of individual measured values.

CHALLENGES IN IMPLEMENTING QUALITY MANAGEMENT:

- Nature of work which involves many parties and stake holders makes the implementation difficult.
- Highways projects and road works are different from the manufacturing industry where bulk lots are produced in the relatively more controlled factory settings. Road projects comprise of a variety of items which are produced in the field. There is large input of different raw material resources which are always liable to vary. Although checks and controls can be put at different levels but the basic level where actual execution initially takes place is extremely important. It has been a long time observation that the quality depends on the attitude and inclination of the contractor towards quality hence it is quite individual- centric.
- Bringing change is difficult due to rigid attitudes and is slow and incremental.
- Lack of will to learn new things.
- Lack of system to have formal trainings.
- The guidelines to quality as already discussed are extensive and detailed. But following these guidelines is not easy if the constructing agencies are not quality oriented then complete enforcement by the supervision engineer is not easy.
- It is a known fact that there is tough competition for works among the contractors. This drives contractors to bid for works at lower rates. Sometimes these rates are not workable and the quality suffers. There is lack of support for rejection of unworkable below par rates.
- As per the provisions of the codes in practice there can only be acceptance or rejection.

- There is no sound framework for incentive based work. The contractors completing works with good quality are treated at par with other contractors in the bidding process. There needs to be a comprehensive grading system for completed works.
- There is no system in place to connect performance with payment.

SUGGESTIONS AND RECOMMENDATIONS:

- Each and every project is unique with its size, scope, time of completion and other constraints. In addition to this the items covered in the scope of work in each infrastructure project are much varied hence it is suggested that each project needs a quality management model based on the specific nature and needs.
- The acceptance criteria of 90% confidence level as per specifications generally set out for different items of work is difficult to achieve without good quality work. Moving towards TQM which also includes approach like quality circle for major works will improve human factor very vital for change.
- There is always a lot to learn from failures. There should be no attempt to hide non-conformance either in “in process” checks or “after process” checks. All cases of non-conformance should be examined and reviewed to implement changes. Quality management is a dynamic process.
- It is imperative to increase the defect liability period to make the contractors quality oriented.
- Contracts should have clear conditions for reduced pay factor in case of sub standard work and the reduction should be substantial.
- Periodic post construction performance audits after 5 or 10 years can be considered linking incentives to the contractor based on the performance. This audit is suggested to take a comprehensive view after considering all the design parameters and the traffic growth also in the project reach.

Feasibility Study of Ferrochrome Slag as an Alternative to Natural Aggregates

P N Ojha, Abhishek Singh, Brijesh Singh, B N Mohapatra

National Council for Cement and Building Materials, Faridabad, Haryana

✉ brijeshsehwaigtr96@gmail.com

ABSTRACT

The utilization of waste generated from any industrial process and conservation of natural resources is one of the main objective of sustainability goal. Ferrochrome slag is waste material obtained from manufacturing of high carbon ferrochromium alloy. Depending upon cooling process, two types of ferrochrome slag are produced i.e. Air cooled by letting molten slag cooled down under normal temperature and water cooled ferrochrome slag by quenching molten slag. Presence of chromium in Cr^{+3} and Cr^{+6} state in ferrochrome slag is an area of concern towards its feasibility to be used as a constituent material in concrete. In this study characterization of both types of slags has been carried out to check the feasibility of replacing natural fine aggregates with water cooled ferrochrome slag and natural coarse aggregates with air cooled ferrochrome slag. In concrete mix designs, natural aggregate has been replaced with ferrochrome slag at percentage of 30%, 60% and 100%. Mixes were prepared at two w/c ratios and fresh & hardened properties of concrete were evaluated. It was concluded that 60% replacement of natural coarse aggregate with air cooled ferrochrome slag and 60% replacement of natural fine aggregate with water cooled ferrochrome slag in concrete is feasible.

Keywords : Ferrochrome slag; characterization; aggregates; leaching.

INTRODUCTION

The Ferrochrome slag is an important byproduct of ferrochromium industries and generated during the manufacturing of ferrochrome alloy. Ferrochrome alloy is manufactured in a submerged electric arc furnace by physiochemical process at the temperature of 1700°C . The main constituents of ferrochrome slag are SiO_2 , Al_2O_3 and MgO with minor traces of ferrous/ferric oxides and CaO . Chromium is generally present in the form of partial altered chromite and entrapped alloy. Quartzite is added as fluxing material to reduce the melting temperature of slag. The slag production is 1.1-1.6 t / t Ferrochrome alloy depending on feed materials.

Depending upon the cooling process, two types of ferrochrome slag are produced i.e. Air cooled by letting the molten slag cooled down under normal temperature and water cooled ferrochrome slag by quenching the molten slag. Due to particle size being in the range of coarse fraction, the air cooled ferrochrome slag can be used as replacement of natural coarse aggregate in concrete. Since, the particle size of water cooled ferrochrome slag is in the range of fine fraction, the water cooled ferrochrome slag can be used as replacement of natural fine aggregate in concrete. However, presence of chromium as Cr^{+3} which is not soluble in water (when oxidized turns into Cr^{+6}) and Cr^{+6} which is soluble in water (hazardous), makes ferrochrome slag a potent threat to environment.

In both water cooled and air cooled ferrochrome slag as determined by Nilamadhaba et.al [1], chromium is present in stable spinel phase and in the form of entrapped metallic granules. In molten slag, Cr is mainly in Cr^{+2} , which is not stable at room temperature and therefore solidifies in most stable oxide i.e. Cr_2O_3 or Cr^{+3} which is insoluble in water and also not expected to oxidize at atmospheric temperature to highly soluble and carcinogenic Cr^{+6} form. The Cr present in entrapped metallic granules is in dispersed state and therefore not expected to leach out when in contact with water. However, many researchers addressed the oxidation of Cr^{+3} to Cr^{+6} in the presence of strong oxidants which results the possibility of slowly releasing Cr^{+6} to environment in the long run. Leachability of heavy metals is the main environmental concern due to possible impacts on human health and environmental pacts.

Lind et. Al [2] investigated that “leaching tests with salt seawater and PH adjusted water reveal low leachability from the slag for most elements. It was also reported that in road construction, there was a low migration of particles from the slag to the under lying soil and that the leaching from the Ferrochrome slag to the groundwater was low for the elements analyzed,

with the exception of potassium. Al Jabri et al. [3] investigated the combined effects of fly ash as cement replacement and ferrochrome slag as aggregate substitute. Cement was replaced with fly ash at the ration of 10, 20, and 30% whereas coarse limestone aggregates were replacing with coarse ferrochromium aggregate at the ratio of 25, 50, and 75%. The results from the study revealed that ferrochromium aggregates increase the strength of concrete and also the abrasive wear resistance while it has negligible influence on the porosity and water absorption of concrete.

Panda et.al [4] investigated the environmental and mechanical properties of concrete. The concrete made with ferrochrome slag shows increased strength as compared to control sample. The standard leaching experimental results showed that the leachable chromium remains well immobilized in the cement and concrete matrix with very low to non-detectable level of chromium leaching. Sathwik et. Al [5] investigated the utilization of ferrochrome slag as replacement of coarse aggregate in concrete. Researcher done the study on M50 grade of concrete. Studies reveal that up to 75% replacement of ferrochrome slag with natural aggregates the compressive and flexural strength are comparable with that of control sample. Zyranov et.al [6] investigated the possibility of low carbon ferrochrome slag into a dry slag and further recycling it into commercial product. Study concludes that strength of concrete under normal condition is less than the strength of concrete under steam curing as high temperature activates the process of slag hydration.

EXPERIMENTAL WORK

Characterization of ferrochrome slag and other concrete making materials was done as per relevant standards. Ferrochrome slag (both water cooled and air cooled) were evaluated for different physical characteristics as per IS: 2386 [7] (as applicable for manufactured sand and manufactured coarse aggregates). Both water and air cooled ferrochrome slag samples were subjected to chemical analysis for evaluation of loss on Ignition, major constituents (Cr_2O_3 , Al_2O_3 , Fe_2O_3 , CaO , SiO_2 , reactive silica and MgO) and minor constituents (Na_2O , K_2O , SO_3 , Cl^- , TiO_2 etc.). Total alkali content as Na_2O equivalent, total sulphate content as SO_2 , acid and water soluble chloride content and total sulphur as S. Elemental analysis and leaching study as per TCLP procedure for heavy metals was carried out for both ferrochrome slag samples. Other concrete making materials such as cement, natural aggregate and admixture were meeting the criteria as mentioned in relevant Indian Standards.

Two control concrete mixes were prepared using OPC along with 100% natural fine aggregates and 100% natural coarse aggregates at two different water-cement ratios of 0.65 and 0.40. Then, mixes were prepared by replacing natural fine aggregates with water cooled ferrochrome slag at 30, 60 and 100% along with 100% natural coarse aggregates at both the water cement ratios. Further, mixes were prepared by replacing natural coarse aggregate with air cooled ferrochrome slag at 30, 60 and 100% along with 100% natural fine aggregates at both the water cement ratios. Thus, a total number of 14 concrete mixes were prepared. All the mixes were studied for fresh properties of concrete such as workability (in terms of slump at 30, 60, 90 and 120 minutes) and air content of concrete as per IS: 1199 [8]. Mixes were also evaluated for compressive strength, flexural strength, split tensile strength, densities, drying shrinkage of concrete and modulus of elasticity of concrete at various ages.

STUDY ON FUNDAMENTAL PROPERTIES OF AIR COOLED FERROCHROME SLAG AND WATER COOLED FERROCHROME SLAG

Physical Characterization of Ferrochrome Slag

Sieve analysis of Water Cooled Ferrochrome slag ferrochrome slag ($< 4.75\text{mm}$), Air Cooled Ferrochrome slag (20 mm and 40 mm) samples was carried out as per IS 383:2016 [9] and the results are given in **Table 1**.

Table 1. Sieve analysis of ferrochrome slag samples

IS Sieve Size	Water Cooled Ferrochrome slag ($< 4.75\text{mm}$) % Passing	Air Cooled Ferrochrome slag, 20mm, % Passing	Air Cooled Ferrochrome slag, 10mm, % Passing
40mm	-	100	-
20mm	-	100	-
12.5	-	-	100
10 mm	100	28	100
4.75 mm	100	1	23
2.36 mm	98	-	5

1.18 mm	79	-	-
600 µm	46	-	-
300 µm	28	-	-
150 µm	15	-	-

The results of physical characterization of Ferrochrome slag samples are given in **Table 2** below.

Table 2. Results of physical characterization of Ferrochrome slag samples

Test Carried out	Water Cooled Ferrochrome slag (<4.75mm)	Air Cooled Ferrochrome slag, 20mm	Air Cooled Ferrochrome slag, 10mm
Specific gravity	2.87	2.99	2.98
Water absorption, %	0.74	0.33	0.31
Material finer than 75µm % (wet sieving)	3.97	0.10	0.1
Soundness, MgSO ₄ %	2.68	1.28	1.91
Organic impurities %	Nil	Nil	Nil
Clay Lumps %	Nil	Nil	Nil
Total deleterious material, % (excluding coal & lignite)	Nil	Nil	Nil
Loose Bulk Density, Kg/lit	1.09	1.61	1.43
Compacted Bulk Density, Kg/lit	1.21	1.71	1.56
Accelerated Mortar Bar, ASTM C1260, %	0.02	0.09	0.09
Abrasion value	-	14	-
Crushing Value	-	19	-
Impact Value	-	15	-

The physical properties of water cooled and air cooled ferrochrome slag meets the various requirements of IS: 383-2016. The specific gravity of slag samples was observed to be higher than that of natural aggregates. Water absorption and material finer than 75 µm were found to be comparable with natural aggregates. The water cooled ferrochrome slag lies in zone 2 of grading as per IS: 383-2016. The low values of abrasion, crushing and impact reflects the stronger nature of air cooled ferrochrome slag.

Chemical Characterization of Ferrochrome slag samples.

Both type of ferrochrome slag samples (water cooled and air cooled) were characterized for several chemical parameters. The results of chemical characterization of ferrochrome slag sample are tabulated in **Table 3** below.

Table 3. Results of chemical characterization of ferrochrome slag samples

Test Carried out	Water Cooled Ferrochrome slag (<4.75mm), %	Air Cooled Ferrochrome slag, (>4.75mm), %
Gain on Ignition, %	+1.51	+0.93
Silica	25.73	31.54
Iron Oxide	3.59	5.23
Alumina	35.3	28.67
Calcium Oxide	2.8	3.68
Magnesium Oxide	22.36	19.22

Sulphuric Anhydride	0.12	0.06
Chloride	0.015	0.01
Alkalies Equivalent as Na ₂ O	0.23	0.55
Titanium Dioxide	1.06	1.44
Reactive silica	21.49	25.24
Water soluble chloride	0.001	0.0018
Total Sulphur	0.25	0.44

The prescribed limit of total alkali content is given as 0.3%. The observed value of alkalis equivalent is 0.23% in case of water cooled ferrochrome slag which lies within the limit specified. However, the value obtained in case of air cooled ferrochrome slag is higher than the prescribed limit. The observed values of chloride content, calcium oxide, iron oxide and total Sulphur are well within the limits.

Elemental Analysis of Ferrochrome slag samples.

Both water cooled and air cooled ferrochrome slag samples were subjected to elemental analysis. The results of elemental analysis of ferrochrome slag samples are tabulated in **Table 4** below.

Table 4. Results of elemental analysis of ferrochrome slag samples

Element	Water Cooled Ferrochrome slag (<4.75mm), %	Air Cooled Ferrochrome slag, (>4.75mm), %
Barium	0.027	0.098
Beryllium	0.001	0.0005
Bismuth	Below detection Limit	Below detection Limit
Cadmium	0.002	0.001
Cobalt	0.012	0.012
Chromium	8	8.86
Copper	0.175	0.42
Gallium	Below Detection Limit	Below Detection Limit
Manganese	0.219	0.185
Molybdenum	0.011	0.008
Nickel	0.032	0.04
Lead	0.013	0.008
Selenium	Below Detection Limit	Below Detection Limit
Strontium	0.088	0.008
Tellurium	Below Detection Limit	Below Detection Limit
Thallium	Below Detection Limit	Below Detection Limit
Zinc	0.029	0.061
Vanadium	0.012	0.013
Chromium, Cr ⁺³	-	-
Chromium, Cr ⁺⁶	0.0002	0.0003

Table 11 of IS: 383-2016 quotes limits for environmental safety and quality standards for using iron, steel and copper slag aggregates. The values obtained for cadmium, lead, selenium and hexavalent chromium are within limits.

Leaching study for heavy metals on ferrochrome slag samples

Leaching study on air and water cooled ferrochrome slag has been conducted as per TCLP procedure. The results of concentration

of heavy metals in slag sample have been tabulated in **Table 5** below.

Table 5. Results of leaching study on ferrochrome slag and natural aggregates

SI No.	Constituents	Water cooled FS Slag FA	Air-cooled FS Slag CA	Limits as per TCLP procedure
1	Chromium	0.486	0.727	5
2	Copper	0.005	*BDL	25
3	Manganese	1.298	1.215	10
4	Nickel	0.831	0.774	20
5	Lead	0.020	BDL	5
6	Zinc	0.208	0.209	250
7	Iron	45.37	53.93	-
8	Titanium	0.012	0.011	-

As per the leachable concentration limits given in ministry of environment [10], forest and climate change guidelines, the observed values are lower than the prescribed limits.

STUDIES ON FRESH, HARDENED AND DURABILITY PROPERTIES OF CONCRETE MIXES

Concrete mixes containing water cooled Ferrochrome slag as replacement of Natural fine aggregate

Two control concrete mixes (M4 and M0) were prepared using OPC along with 100% natural fine aggregates and 100% natural coarse aggregates at two water-cement ratios of 0.65 and 0.40. Then, mixes were prepared by replacing natural fine aggregate with water cooled ferrochrome slag at 30, 60 and 100% along with 100% natural coarse aggregates at both the water cement ratios

Therefore, a total of 8 mix designs (2no. of control mixes + 3 x 2 = 6 number of mixes containing water cooled ferrochrome slag as fine aggregate) were carried. The concrete mixes were designed for initial slump value of around 150mm. Mix design details of concrete mixes are tabulated in **Table 6**.

Table 6. Concrete mix design details of mixes containing water cooled Ferrochrome slag as replacement of Natural fine aggregate

S. No.	Mix	Ferrochrome slag as fine Aggregates (%)	Cement (Kg/m ³)	Water (Kg/m ³)	Ferrochrome slag as fine Aggregates (%)	Natural Fine aggregate(Kg/m ³)	Natural Coarse Aggregate (10 mm) (Kg/m ³)	Natural Coarse Aggregate (20 mm) (Kg/m ³)	Admix (%)
1	M4	0	300	195	0	874	414	623	0
2	M1	30	300	195	287	611	413	622	0.2
3	M2	60	300	195	573	349	413	621	0.7
4	M3	100	300	195	957	0	413	622	0.2
5	M0	0	425	170	0	773	439	661	0.2
6	M5	30	425	170	254	541	439	661	0.3
7	M6	60	425	170	507	309	439	660	0.5
8	M7	100	425	170	847	0	439	661	0.2

Fresh Concrete Properties

Fresh concrete properties such as workability (in terms of slump at 0 minutes, 30 minutes, 60 minutes and 120 minutes after preparation of mix) and air content were evaluated for all the 8 mixes and test results are given in **Table 7**.

Table 7. Fresh Concrete Properties of mixes containing water cooled Ferrochrome slag as replacement of Natural fine aggregate

S. No	W/c Ratio	Mix ID	Ferrochrome slag as fine Aggregates (%)	Natural Sand	Workability of concrete (mm)				Air Content, %	Remarks
					0 Min	30 Min	60 Min	120 Min		
1	0.65	M4	0	100	145	135	125	100	1.8	Homogeneous mix
2	0.65	M1	30	70	150	120	100	55	1.9	
3	0.65	M2	60	40	160	110	85	30	2	
4	0.65	M3	100	0	140	120	90	40	2.1	Segregation and bleeding
5	0.4	M0	0	100	150	140	120	90	1.7	Homogeneous mix
6	0.4	M5	30	70	150	110	80	40	1.9	
7	0.4	M6	60	40	145	100	60	30	2.1	
8	0.4	M7	100	0	150	110	80	40	2.4	Segregation and bleeding

Concrete mixes containing Ferrochrome slag showed significantly higher slump loss after 60 and 120 minutes in comparison to the control concrete mixes. Air content of all 8 mixes were similar and comparable (around 2%). It was observed that when replacement of natural coarse aggregate with air cooled ferrochrome slag goes beyond 60%, mixes showed signs of segregation and bleeding due to high specific gravity of ferrochrome slag.

Hardened Concrete Properties

Hardened concrete properties were evaluated for the eight concrete mixes. Compressive strength test was conducted on concrete cubes (size 150 mm) as per IS: 516 [11]. Flexural strength test was conducted on concrete beam (size 500mm x 100mm x 100mm) as per IS: 516. Split strength test and Modulus of Elasticity were conducted on concrete cylinder (150mm diameter and 300mm height) as per IS:5816 [12] and IS:516 respectively. Drying shrinkage test was conducted on concrete beam (75 x 75 x 300 mm) as per IS:1199. The test results are in **Table 8**.

Table 8. Hardened Concrete Properties containing of mixes containing water cooled Ferrochrome slag as replacement of Natural fine aggregate

W/c	Mix ID	Ferrochrome slag as fine Aggregates (%)	Compressive Strength, MPa				Flex Strength, MPa		Split Tensile Strength, MPa	Dry Density Kg/m ³	Drying Shrinkage	MOE (N/mm ²)
			1 Day	3 Day	7 Day	28 Day	7 Day	28 Day				
0.65	M4	0	4.54	12.5	18.1	26.22	4.07	5.05	2.42	2450	0.0171	28204
0.65	M1	30	6.33	14.5	20.2	30.14	4.4	5.3	2.67	2470	0.0168	30651
0.65	M2	60	7.38	16.5	22.95	38.05	5.07	5.37	2.72	2550	0.0164	32982
0.65	M3	100	8.67	18.8	24.46	41.89	5.45	6.01	3.21	2502	0.0179	34876
0.4	M0	0	15.95	32	41.86	49.79	6.4	8.07	4.51	2478	0.0191	37144
0.4	M5	30	19.05	27.2	43.01	46.75	6.37	9.77	4.75	2494	0.018	38013
0.4	M6	60	20.84	29.3	42.89	53.08	7.17	10.3	5.1	2520	0.0175	38885
0.4	M7	100	23.76	27.8	44.78	56.89	8.5	11.4	5.26	2560	0.0173	40016

Compressive, flexural and split tensile strength at age of 28 days for experimental mixes (containing water cooled ferrochrome slag as replacement of fine aggregates) at both w/c were found to be either higher or comparable to their control mix. Due to higher specific gravity of ferrochrome slag, dry density of the concrete mixes containing water cooled ferrochrome slag were higher than control mixes. The drying shrinkage values for all the concrete mixes were found satisfactory and comparable with their corresponding control mixes. Modulus of Elasticity (MOE) of the concrete mixes containing ferrochrome slag as

replacement of natural fine aggregates were found to be either higher or comparable to corresponding control mixes

Concrete mixes containing air cooled Ferrochrome slag as replacement of Natural coarse aggregate

Along with two control concrete mixes (M4 and M0), mixes were prepared by replacing natural coarse with air cooled ferrochrome slag at 30, 60 and 100% along with 100% natural fine aggregates at both the water cement. Thus, six experimental mixes (containing air cooled Ferrochrome slag) were prepared along with two control mixes. All the concrete mixes were designed for initial slump value of around 150mm. Mix design details of concrete mixes are tabulated in **Table 9**.

Table 9. Concrete mix design details of mixes containing air cooled Ferrochrome slag as replacement of Natural coarse aggregate

Mix	Ferrochrome slag as coarse Aggregates (%)	Cement (Kg/m ³)	Water Kg/m ³	Natural Fine aggregate (Kg/m ³)	Ferrochrome slag as coarse Aggregate (10mm) (Kg/m ³)	Ferrochrome slag as coarse Aggregate (20mm) (Kg/m ³)	Natural Coarse Aggregate (10 mm) (Kg/m ³)	Natural Coarse Aggregate (20 mm) (Kg/m ³)	Admix (%)
M4	0	300	195	874	0	0	414	623	0
M8	30	300	195	863	116	217	286	431	0

M12	60	425	170	759	245	457	172	260	0.3
M13	100	425	170	759	409	762	0	0	0.3

Fresh Concrete Properties

Fresh concrete properties such as workability and air content were evaluated for all the 8 mixes. Test results are given in **Table 10**.

Table 10. Fresh Concrete Properties of mixes containing air cooled Ferrochrome slag as replacement of Natural coarse aggregate

S. No	W/c Ratio	Mix ID	Ferrochrome slag as fine Aggregates (%)	Natural coarse aggregates	Workability of concrete (mm)				Air Content, %	Remarks
					0 Min	30 Min	60 Min	120 Min		
1	0.65	M4	0	100	145	135	125	100	1.8	Homogeneous mix
2	0.65	M8	30	70	150	140	120	80	1.7	
3	0.65	M9	60	40	150	130	110	50	1.8	
4	0.65	M10	100	0	150	120	70	50	2	Segregation and bleeding
5	0.40	M0	0	100	150	140	120	90	1.7	Homogeneous mix
6	0.4	M11	30	70	150	135	110	70	1.6	
7	0.4	M12	60	40	140	125	90	40	1.9	
8	0.4	M13	100	0	145	90	60	50	2.1	Segregation and bleeding

Concrete mixes containing air cooled ferrochrome slag showed significantly higher slump loss after 60 and 120 minutes in comparison to the control concrete mixes. Air content of all 8 mixes were similar and comparable (around 2%). It was observed that when replacement of natural coarse aggregate with air cooled ferrochrome slag goes beyond 60%, mixes showed signs of segregation and bleeding due to high specific gravity of ferrochrome slag.

Hardened Concrete Properties

Hardened concrete properties were evaluated for all the six concrete mixes (M8 to M13) along with the control mixes (M4 and M0). Specimen size, test method and age of testing for all the tests were kept same as discussed in 4.1.2. Test results have been tabulated in **Table 11**.

Table 11. Hardened Concrete Properties containing of mixes containing air cooled Ferrochrome slag as replacement of Natural coarse aggregate

W/c	Mix ID	Ferrochrome slag as fine Aggregates (%)	Compressive Strength, MPa				Flex Strength, MPa		Split Tensile Strength, MPa	Dry Density Kg/m ³	Drying Shrinkage	MOE (N/mm ²)
			1 Day	3 Day	7 Day	28 Day	7 Day	28 Day

0.4	M13	100	11.92	29.9	37.18	45.39	4.73	6.93	3.87	2560	0.0167	33854

Compressive, flexural and split tensile strength at age of 28 days for experimental mixes (containing air cooled ferrochrome slag as replacement of coarse aggregates) at both w/c were found to be similar and comparable to their control mix. Due to higher specific gravity of ferrochrome slag, dry density of the concrete mixes containing air cooled ferrochrome slag were higher than control mixes. The drying shrinkage values for all the concrete mixes were found satisfactory and comparable with their corresponding control mixes. Modulus of Elasticity (MOE) of the concrete mixes containing ferrochrome slag as replacement of natural coarse aggregates were found to be similar and comparable to corresponding control mixes.

Leaching Studies on Selected Concrete Mixes

Leaching study was also conducted on few selected concrete samples made with replacement of natural aggregates with corresponding ferrochrome slag aggregates, as per Toxicity Characteristic Leaching Procedure (TCLP) to detect the presence of different heavy metals constituents. The results of concentration of heavy metals ions leached out from concrete samples are given in **Table 12**.

Table 12. Results of Leaching study on concrete samples

SI No.	Constituents	M0	M1	M4	M5	M6	Limits as per TCLP procedure
1	Chromium (Cr)	0.010	0.119	0.1341	0.169	0.187	5
2	Copper (Cu)	0.006	0.047	0.009	0.12	0.007	25
3	Manganese (Mn)	0.002	0.025	0.002	0.002	0.002	10
4	Nickel (Ni)	BDL	0.023	0.013	0.007	BDL	20
5	Lead (Pb)	BDL	BDL	BDL	BDL	BDL	5
6	Zinc (Zn)	0.035	0.053	0.039	0.028	0.034	250
7	(Fe) Iron	0.048	0.032	BDL	0.010	0.001	-
8	Titanium (Ti)	0.003	0.92	0.054	0.028	0.053	-

As per the leachable concentration limits given by ministry of environment, forest and climate change guidelines, the observed values of heavy metal ions are lower than the prescribed limits.

CONCLUSIONS

Based on the results and observations of above mentioned studies following conclusions can be drawn:

- a) Physical properties of water and air cooled ferrochrome slag meets the various requirements of IS: 383-2016. Specific gravity of slag samples was observed to be higher than that of natural aggregates. Water absorption and material finer than 75 μm were found to be comparable with natural aggregates. The low values of abrasion, crushing and impact reflects the stronger nature of air cooled ferrochrome slag.
- b) The results of elemental analysis of ferrochrome slag samples showed that concentrations of elements are within limits.
- c) Concrete mixes were prepared at two w/c ratios by replacing natural fine aggregates with water cooled ferrochrome slag and natural coarse aggregates with air cooled ferrochrome slag. Concrete mixes containing Ferrochrome slag showed significantly higher slump loss after 60 and 120 minutes in comparison to the control mixes. It was observed that when replacement of natural aggregates with ferrochrome slag goes beyond 60%, mixes showed signs of segregation and bleeding due to high specific gravity of ferrochrome slag. Hardened properties of concrete mixes containing ferrochrome slag were found to be higher or comparable to their corresponding control mixes at the age of 28 days.
- d) Leaching study was conducted on water and air cooled Ferrochrome slag as per Toxicity Characteristic Leaching Procedure (TCLP) to detect the presence of different heavy metals constituents such as Cr, Fe, Zn, Cu, Mn, Ni, Pb and Ti. The observed values of heavy metal ions are lower than the prescribed limits. Leaching study was also conducted on few selected concrete samples made with replacement of natural aggregates with corresponding ferrochrome slag aggregates and the observed values of heavy metal ions are lower than the prescribed limits.

Based on the above conclusions, following recommendations are being made:

Water cooled Ferrochrome slag can be used as replacement of natural fine aggregate up to 60% by weight along with 100 % with natural coarse aggregates for making concrete. Air cooled Ferrochrome slag can be used as replacement of natural coarse aggregate up to 60% by weight along 100 % with natural fine aggregates for making concrete.

ABSTRACT

A novel building material that breaks the frailty criteria of the brittle nature of concrete, comprises of eco-friendly sustainable materials as ingredients is called as “Engineered Geopolymer Composites (EGC).” In the scenario of the material development stage of EGC, researchers need to focus on the application of various sustainable materials that are locally available, in the production of EGC, without compromising the mechanical performance. A prediction tool, that helps to forecast the performance of the designed material with the mix-design criteria, would help the researchers for more advanced research; and practicing engineers to decide upon structural applications in the field. ANN and ANFIS have been used in this study to develop the predictive models to estimate the compressive strength performance of EGC. Totally 110 data sets have been prepared from EGC material researches with 6 mix-design influences as inputs, to facilitate the training and validation process of the predictive models. The validated results are analyzed. The research study reveals that the ANN model has predicted the compressive strength of EGC with the accuracy of 78% with RMSE 3.3 whereas ANFIS showed a prediction of about 86% accuracy with RMSE 3.03.

Keywords : ANFIS; ANN; Engineered geopolymer Composites; Flexible concrete; Prediction; Strain hardening composites.

INTRODUCTION

Interdisciplinary research has become popular in almost all kinds of research fields. Especially the usage of electronics and Information technology in accounting, material design, machine designs, labour managements, navigation etc., The most notable thing in the field of the construction industry is the application of artificial intelligence in concrete material design. The development of predictive models with various soft-computing techniques (SCT) or machine learning models have helped various researchers and practicing engineers to prejudge the outcome of design or research progress without actually experimenting it. Significant SCTs include Neural Networks, Fuzzy logic, Genetic algorithm etc., that facilitated to predict the mix-design, strength and workability parameters in various kinds of special concrete composites.

Artificial Neural Networks (ANN) and Adaptive Neuro-Fuzzy Inference System (ANFIS) are the most popular tools among AI, particularly in the application of concrete technology from the early 2000s. These are based on real-life concepts, generated artificially, to solve problems on optimization, prediction, forecast etc. ANN works on the principle of interconnected neurons in the human brain. ANN network consists of an input layer, hidden layer and an output layer, interconnected with neurons. Speaking mathematically, starting with an input variable across the hidden layer bridged with ‘weights’ towards output variable forms an empirical equation. During the training process, the weights upon the variables keep on changing continuously until a suitable equation with maximum accuracy will be obtained. With that established equation, prediction can be done. ANFIS is a combination of ANN and Fuzzy logic (FL). FL works on the principle of ‘IF-THEN’ rule sets. FL has various types and numbers of membership functions (MF), based on which it forms different ‘rule sets’, e.g., “IF input-1 is very low, input-2 is medium and input-3 is high; THEN the output is very low”

Thus, based on the number of inputs; the number of MF and the type of MF, the ANFIS system generates large ‘rule sets’ from which the output values will be predicted.

Researchers focus on two major drawbacks in cement concrete in terms of environmental and material strength aspects. Usage of cement binder in concrete affects the environmental conditions near the manufacturing unit of cement, as it releases huge greenhouse gases like carbon-di-oxide into the atmosphere, when raw materials are burnt at very high temperature in the clinker. In ‘strength of materials’ point of view, concrete is weak upon tensile force due to its brittle nature, because of which the deformation in concrete occurs instantly thereby giving least warning to the occupancies.

A recent novel building material that is tailored to overcoming aforesaid drawbacks of the conventional concrete is popularly known as 'Engineered Geopolymer Composites' (EGC). EGC is the hybrid combination of Engineered Cementitious Composites (ECC) and Geopolymer Concrete (GPC). ECC is a kind of ultra-high ductile fiber reinforced cementitious composites that uses a special synthetic fiber called Polyvinyl alcohol fiber (PVA) that enhances the ductility of the material. The material ingredients of ECC are tailored in such a way that the fiber bridging capacity is greater than the matrix toughness post-first crack, thereafter leads to the formation of multiple cracks (micrometer crack width) thereby enhances strain-hardening criteria. Because of this peculiar property, the concrete composite attains flexible nature, thus it is also known as "Flexible concrete".

Replacing the cement in ECC with Geopolymer binder which is 100% eco-friendly sustainable materials, is called as EGC. Thus, EGC, which comprises of 100% eco-friendly material ingredients that overcome the brittle failure of conventional concrete, serving both environmental and technical aspects. The recent researches on ECC and EGC material behaviour have been summarized in the literature review section. This paper attempts to apply artificial intelligence tool(s) that would facilitate the researchers around the world for advanced EGC material research.

Literature Review

Material research on EGC has started a decade back. Researches tried to develop EGC material with various industrial by-products in mixed proportions. Kan et al [1] have used Metakaolin and Flyash in mixed proportions and obtained the maximum strain capacity of 6.8%. 100% Metakaolin was used by Ekatpuri et al [2] with varying volume fractions of PVA fiber and it reveals that 0.6% Volume fraction was optimum. Ling et al [3] used slag along with ash i.e., Ground Granulated Blast furnace Slag (GGBS) and Flyash in mixed proportions and the optimum was 80% flyash with 20% GGBS. Some notable variations on PVA fibers and fine aggregate have also been carried out by the researchers which include lightweight fillers like expanded perlites [4]; and some micro-fibers like polypropylene fibers are added along with PVA fibers [5].

Initially, in the early 2000s, ANN has been used to predict the compressive strength of concrete [6] and prejudge the workability by estimating the slump of concrete. [7]. Later, keeping the strength and/or workability as inputs, researchers have analyzed the mix-design contents, thereby engineers can alter the material proportions to obtain the desired strength. Generally, the literature reveals that ANN gives maximum accuracy in prediction to the range 80-95%. Similarly, the ANFIS tool has also been used in similar applications as that of ANN. Sadrmomtazi et al [8] have predicted the compressive strength of lightweight concrete using ANN and ANFIS models it is concluded that bell-shapes membership function has produced the accuracy level of 98%. Vakhshouri et al [9] have estimated the compressive strength of high strength self-compacting concrete and they reveal that ANFIS established a strong correlation between mix-factors and strength.

Need for Study

The main fact to be analysed before involving the usage of GPC in construction is the 'local availability' of concrete ingredients. GPC uses any kind of alumino-silicate based industrial by-products like Flyash, GGBS, Metakaolin, Silica fume etc., as a binding material; where each material has its peculiar merits and demerits on mechanical properties of the GPC composites. For instance, Flyash based GPC is known best for its better mechanical and workability performances, whereas GGBS based GPC gives excellent strength parameters. In such a case, practising engineers might need to have a preliminary decision making upon the usage of those locally available alumino-silicate material(s) that suits for the mix-design purpose, structural applications and site conditions. For any mix-design process of concrete composites, compressive strength is the prior criteria that need to be satisfied. Predicting the minimum compressive strength that can be obtained, with the available ingredients and the predefined mix design criteria, would help the practising engineers to make decisions on using those locally available concreting ingredients in mix-design of GPC. In this paper, based on the application of AI tools, suitable predictive models are needed to be developed with higher accuracy which would enhance the above-mentioned decision-making criteria to the practising engineers in the field. It also facilitates various researchers on material EGC to select the concreting ingredients for advanced materials research on EGC, thereby reducing the cost and time for experimental procedures.

Preparation of Database & Development of Predictive models

Based on the literature survey, it is clear that, among the SCTs, ANN and ANFIS perform greater in predicting the compressive strength of concrete composites particularly when the mix-design influencing parameters are lesser. This paper tries to attempt the usage of AI tools – ANN and ANFIS in developing the predictive models to anticipate the magnitude of compressive strength of the material EGC.

1) Database: Initial database is required for training the predictive models and thereby validating the models to check the accuracy of prediction. The database is collected from various research publications around the world. These researches are based on PVA fibre-reinforced GPC with binding materials as Class F flyash and/or Metakaolin based Geopolymer paste (no

fine aggregate contents are involved in those material research). Sodium based alkali activators with the combination of sodium hydroxide and sodium silicate has been used in those literatures. The specimens are treated under elevated temperature for a few hours before ambient curing (for a certain number of days) before testing.

Totally, 110 data set has been prepared from various literatures [1-5,10-12] with aforesaid testing conditions, for training and validation of the predictive models. Among which 90 data set has been used for training the models and the subset of the 20 data set has been used for validating the models. To ensure the accuracy of prediction, the literatures have been selected in such a way that no additional parameters (includes additional binding materials other than flyash and metakaolin; additional admixtures or fine aggregate contents) have been included in the testing of the literatures. The mix-design factors which are selected as input parameters to the prediction, along with mean, standard deviation, maximum-minimum range is summarized in Table I. The input parameters mentioned in **Table 1** is described as follows, FFA - Class F flyash content (kg/m³), MK - Metakaolin content (kg/m³), PVA - volume fraction of PVA fiber in %, ACT- activator to binder ratio, CT - temperature of heat curing (°C), ACD - Ambient curing temperature duration in days; SD - standard deviation.

Table 1. Inputs for training and validation

Input Parameters	Training				Validation			
	Min	Max	Mean	SD	Min	Max	Mean	SD
FFA	0	1029	85.1	235	0	850	126	256
MK	0	890	761	312	0	890	702	362
PVA	0	3	0.7	0.7	0	2	0.8	0.7
ACT	0.27	0.89	0.8	0.2	0.27	0.89	0.8	0.2
CT	25	80	53.9	19.9	25	80	50.5	22.7
ACD	3	56	19.8	16.7	3	56	22.6	19.2

2) Creating ANN & ANFIS models: ANN and ANFIS predictive models have been developed using MATLAB application software. The functions involved in MATLAB for creating and analyzing the ANN and ANFIS models are ‘nntool’ and ‘anfisedit’ respectively. For creating ANN & ANFIS models, few preliminary design-data are needed to be specified, that suits best intended for the purpose of creating the models. For instance, specifying the number of hidden neurons, type of ANN network, no. of epochs etc., are needed to be specified initially. For creating ANN models, the following design-data parameters are specified, (considered based on literatures) such as Levenberg-Marquardt (trainlm) type ANN network, one layer of hidden neurons, Feed-forward Back Propagation type, Number of epochs-10000, Max fail-10000. A tedious task here is to select the number of hidden neurons. The number of hidden neurons in the hidden layer is always influenced by the number of input parameters. Since the number of input parameters is 6, the number of hidden neurons is varied from 4 – 10 and the best number has been identified based on trial and error method. Here, regression function during the training process has been used to analyze the ANN models and the best ANN model has been chosen as ANN-5 (which indicates ANN network with 5 hidden neurons in the hidden layer) which is also represented as ANN [6:5:1] (no of inputs: no. of hidden neurons: no of outputs). The software randomly takes 70% of the training dataset for self-training, 15% of the data for self-testing and 15% of the data for self-validation. The overall regression and best validation performance of the ANN-5 model during the training process have been illustrated in **Fig. 1**. After this training process, the outputs for validation has been simulated.

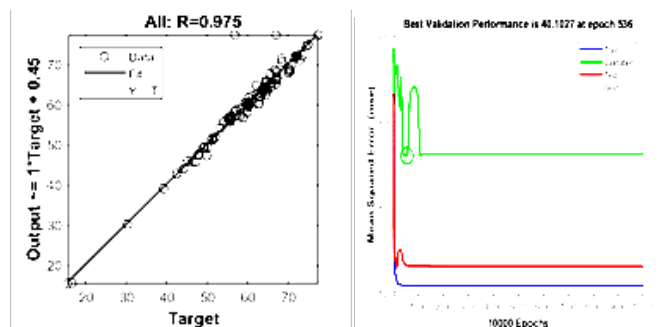

Fig. 1. Regression during training process and Best validation performance

Similarly, while creating the ANFIS model in MATLAB the following design-data are specified which includes, ‘Grid partition’ type of FIS, 3 numbers of MF, ‘Triangular’ type of MF, ‘hybrid’ optimization method and 10 number of epochs. The accuracy of the progress can be viewed during the training process through the chart shown in **Fig. 2**. Blue circles indicate the actual values and Red star indicates the predicted values, overlapping of those two indicates the greater accuracy in the training process of ANFIS. Validation outputs can then be obtained using ‘evalfis’ function.

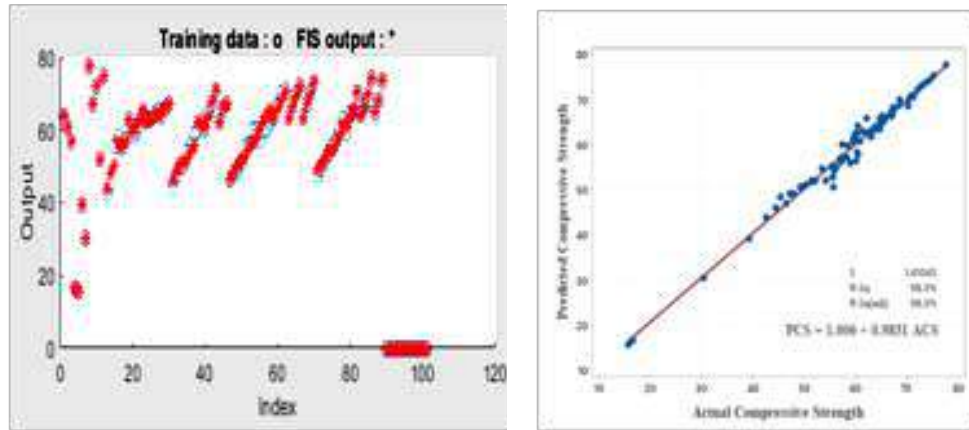

Fig. 2. Accuracy plot & R2 during training of ANFIS

RESULTS AND DISCUSSIONS

1) Validation of ANN and ANFIS: **Table 2** gives the predicted output results of compressive strength of Engineered geopolymer composites with ANN and ANFIS tools, compared to the actual compressive strength values from the literature, with the results of the coefficient of determination, Magnitude of residue and the Root mean squared error.

As it is clear from table II that, ANN and ANFIS had shown excellent potential in predicting the compressive strength of EGC. The overall accuracy obtained can be inferred from the co-efficient of determination (R2) value. **Fig. 3** shows the plot between the actual compressive strength and the predicted compressive strength of ANN and ANFIS models with the regression line of fit and co-efficient of determination during the validation process. It is observed that the ANN model has shown 97% accuracy in the training process (**Fig. 2**) and 78% accuracy in prediction during validation (**Fig. 3**).

Table 2. ANN and ANFIS predicted outputs of validation with R2 and RMSE

	R ²	0.78		R ²	0.86
	RMSE	3.31		RMSE	3.01

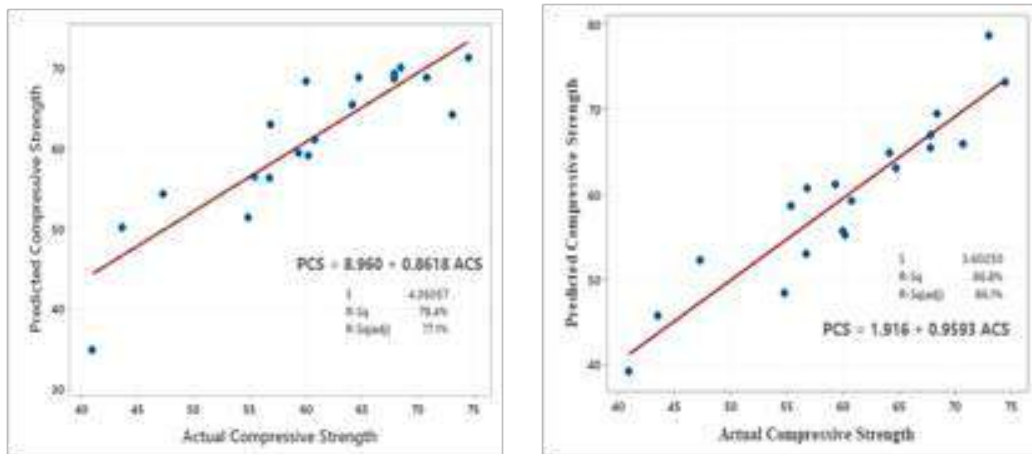

Fig. 3. Coefficient of determination of ANN and ANFIS models

The foremost thing to be considered during the prediction of compressive strength of concrete composites is the magnitude of residue between the actual and predicted values. During the mix-design process of concrete, it is mandatory to achieve the minimum compressive strength required, whereas the maximum strength achieved by the design is secondary. Thus, during the prediction process, the number of positive residues to be given prior importance than the number of negative errors. It is observed that 42% of the validation data set have shown positive errors, but it is also to be noted that the range of those positive error lies within 0 to 2, and the RMSE obtained is 3.31 which is phenomenal. The maximum positive error obtained from the ANN model validation is 8.8, which is quite not acceptable for sensitive parameters like compressive strength of EGC. The overall accuracy obtained during the validation of the ANN model is 78%, which is comparatively less accurate than ANN predictive models of other special concrete of estimating the compressive strength. Generally, there are no restrictions on the number of input parameters for ANN models, therefore all the mix-design influences affecting the compressive strength can be taken into account as inputs and it is also to be noted that, more the number of inputs and database more will be the accuracy of the prediction of ANN models.

ANFIS tool has also shown the excellent potential of predicting the compressive strength of EGC, since the RMSE has obtained as 3.01 i.e., the ANFIS tool has the ability to predict the compressive strength with the approximate error of ±3. Fig. 3 shows the comparative plot between the actual compressive strength of the experimental results from the literatures and the predicted values from the ANFIS of validation data set by which the coefficient of determination R² value is computed. Here, the ‘test data’ represents the prediction of output with the input data that were used to train the ANFIS model (Fig. 2) whereas the ‘validation data’ represents the output predicted for the inputs from the validation data set (Fig. 3). Thus the ‘test data’ indicates the accuracy of the training process and the ‘validation data’ indicated validation accuracy of ANFIS model. The coefficient of determination values shows that with 90 training data set, the ANFIS tool can able to train itself to the accuracy of nearly 98% (R² = 0.9831). The trained ANFIS model can now be able to predict the compressive strength of the validation data set (19 data set) with the accuracy of about 86.4%. The magnitude of residues obtained within the range of 0 to 2 is about 57% and the maximum positive residue obtained is 6.4 which is comparatively acceptable. As far as the ANFIS tool prediction is concerned, the grid-partition type FIS accepts a limited number of input parameters and the prediction accuracy can be obtained around 90%.

CONCLUSIONS

ANN and ANFIS models have been created, trained and validated with the databases prepared from various literature. ANN [6:5:1] model and Grid-partition based FIS model has been used in this study and the following conclusions are made.

- The ANN model with one hidden layer with 5 number of hidden neurons was the best among other ANN models (with other hidden neurons) and the model has shown 78% accuracy in the validation, based on the coefficient of determination with RMSE 3.3.
- Grid-partition based ANFIS model has shown the accuracy of 86% based on R2 during the validation process with RMSE 3.03.
- With the limited number of input parameters (fewer mix influences), ANFIS can predict the compressive strength of EGC with greater accuracy, whereas, ANN can produce maximum accuracy when the number of input parameters are more with a large database.

ABSTRACT

Infrastructure spurs the economic growth of any nation. All over the world, infrastructure projects are known for their cost and time overruns and India is no exception. Owing to plethora of risks, infrastructure projects get bogged down and in the absence of proper risk management mechanism, most of the project plans go haywire. This leads to such a situation wherein the project would have taken a substantially long period to reap the benefits by which time the financial calculations would have gone awry. Ultimately majority of the infrastructure projects become a drag on a nation by way of substantial investment with returns not fructifying in a timely manner. This paper analyses the risk mitigation mechanisms that were undertaken in a Thermal Power Project in the state of Andhra Pradesh that led to success of the project in terms of cost and time under run.

Keywords : Risk management; Risk mitigation.

INTRODUCTION

The role of infrastructure in spearheading economic development of a country and also setting its pace can hardly be over emphasised. The economic growth of a country progresses with the development of its infrastructure. A sound infrastructural foundation is the key to the overall socio-economic development of a state. Infrastructure encompasses the whole spectrum of vital services such as roads, railways, civil aviation, shipping, power generation transmission, telecommunications, postal facilities and urban development. Infrastructure facilities act as a catalyst for rapid achievement of sustainable economic growth. Infrastructure has a two-way relationship with economic growth i.e infrastructure promotes economic growth, and economic growth brings about changes in infrastructure. The management of risks in infrastructure projects becomes all the more important given the propensity of an infrastructure project to experience plethora of risks. The more effective risks management mechanism is in place, to that extent an infrastructure project is insulated from risks.

LITERATURE SURVEY

- 1) Abhishek V Jadhav et al (2010) on “A Study of Risk Involved in Execution and Management of Thermal Power Station – A Case Study” have investigated on the various risks in the project taken up for study and concluded that construction and operational risks pose the highest risks in a thermal power project and hence suitable identification and mitigation of these risks can bring down the cost of the project to a substantial extent
- 2) Akintoye et al (1997) in their study on “Risk Analysis and Management in Construction” has revealed that risk analysis and management in construction industry is dependent on three factors i.e 1) Experience 2) Judgement and 3) Intuition of team members. Unfortunately, formal activities to analyse and manage risk are rarely used in construction industry. This main reason for this is the ignorance of project teams towards such techniques and the associated myths that these techniques are unsuitable for use in construction industry
- 3) Avinash Bogale et al (2006) on “Risk Management – A Comparative Study of Power Generating Resources and Technology” have researched on similar risk parameters in Thermal/Hydel/Nuclear power stations and concluded that construction and operating risks contributed to nearly 65% of risks in a thermal power plant.
- 4) Astak et al (2000) conducted a study in which they made broad categories of construction risks i.e Project, Market and Country level risks. Country risks are associated with macroeconomic stability of the country and are linked with the monetary and fiscal policy of the country and the resistance of the country against economic viability. Market risks involve technical advantage of the firm over local competitors, availability of construction related resources and Government support at both local and foreign level towards construction industry. Project level risks are specific to the project activities and they include improper project

design, safety measures for construction site, constraints of logistics, improper control of quality and environmental protection etc They developed a model named ICRAM for assessment of risks.

5) Divya Gupta et al (2015) on “Risk Management in Construction Projects of Developing Countries” have analysed the levels of risk factors in construction industry and concluded that financial risk, defective design, delayed payment on contracts and preparation of feasibility report were the risk factors which had influence in the projects.

6) Eweline Gajewska et al (2011) on “Risk Management Practices in a Construction Project- A Case Study” in Sweden have researched on application of risk management in early stage of life cycle of a construction project have concluded that unstructured risk management is used in construction sector and knowledge and attitude is the missing factor in organisations for implementing risk management and adhoc risk mitigations practices were widely practiced.

7) Kolhatkar M J et al (2014) in the paper on “Risk Management in Construction Projects”, studied the construction industry’s perception of risk associated with the activities and the extent to which industry uses risk analysis and management techniques with the help of questionnaire survey of general contractors and Project Managers. The authors concluded that risk management is essential in construction activities in minimising losses and enhancing profitability. They found that Risk Analysis and Management depends on intuition, judgement and experience and formal risk analysis and management techniques are rarely used due to lack of knowledge and because of doubts over the suitability of these techniques for construction industry activities.

9) Lei Bing et al (2001) in a survey on “Risk Management of International Construction Joint Ventures”, three main groups were made to identify risk factors namely external, internal and project specific. The study examined some cases where risk mitigation measures were used effectively by construction professionals in East Africa. An international survey of contractors revealed that the most critical risk factors existed in the financial aspects of joint ventures, Government policies, economic conditions and project relationships.

10) Shahid Iqbal et al (2015) on “Risk Management in Construction Projects” have dealt on the various risks faced in construction industry and the study revealed that financial issues, accidents at site, defective design are the most significant risks affecting the construction projects and that preparation of proper schedule , good coordination during the implementation stage and suitable preventive risk management techniques are the most effective techniques of risk management.

11) Uher et al(1999) researched cases from Australian construction industry where risk management was used in the conceptual phase of project development. They found that although a majority of respondents had familiarity with risk management processes and techniques and inspite of their willingness to adapt these techniques, risk management was rarely used in the conceptual phase of construction projects

14) Walke R C et al (2011) on “ An Approach to Risk Quantification in Construction Projects Using Expected Monetary Value (EMV) Analysis” have investigated on effective system for risk quantification in construction projects based on EMV analysis and concluded that even though the system does not give a detailed quantitative analysis of risks, it can be fairly used for decision making at commencement of every phase of the project. This technique is sparingly used for quantification of risks

15) Zhen-Yu Zhao et al (2009) in their paper titled “Risk Management of Thermal Power Construction Projects in China – A Case Study” have spelt the increasing need of risks identification and management during the development and construction process of power projects. Using expert investigation method, the preliminary project risk list was obtained and key risks were identified. To deal with the identified high risk factors, a batch of risk controlling and monitoring measures and strategies were proposed. They concluded that a comprehensive and a systematic study of risk management during feasibility study stage will help reduce risk probability and the losses due to these risks. This enhanced the effectiveness of risk management

RISK MANAGEMENT IN CONSTRUCTION PROJECTS

Risk Management is the identification, assessment, and prioritisation of risks followed by coordinated application of resources to minimise, monitor, and control the probability and/or impact of unfortunate events / to maximize the realization of opportunities. Risk management is a systematic way of looking at areas of risk and consciously determining how each should be treated. It is a management tool that aims at identifying sources of risk and uncertainty, determining their impact, and developing appropriate management responses. Risk management consists of 1) risk identification 2) Risk assessment and 3) Risk Mitigation.

DATA COLLECTION

Data for this study was collected by way of questionnaires administered to various stakeholders in a project i.e Client, Contractors

and Consultants. The questionnaires were sent to 500 respondents and the response received was 220 (44%). The respondents were asked to identify the likely risks in various phases of the project i.e pre-investment phase, investment phase, execution phase and closing out phase and also qualitative opinion regarding the contribution of each risk to delay in each phase of the project. Total of 30 such risks were identified. The qualitative opinion to be given by each respondent were 1) Strongly Agree 2) Agree 3) Disagree 4) Strongly Disagree. The Research analysis was carried out subsequently with the help of collected data.

DATA ANALYSIS

The details of the responses received from the respondents are presented in the following Tables. The values in table indicate the opinion of respondents in percentage.

Table 1. Perception of respondents for risks in pre-investment phase

Sl.No	Risk	Strongly agree (%)	Agree (%)	Disagree(%)	Strongly Disagree (%)
1	Land acquisition	33	45	20	3

8	Delay in Grant of Approvals for commissioning	55
9	Legal Restrictions	54
10	Geological Surprises	48

RISK MITIGATION

- The primary source of risk i.e land acquisition was done in a smooth manner by paying an amount 5 times the market price. Thus the risk was suitably mitigated.
- Finalisation of consultants which is a time consuming activity was completed quickly and the consultants were selected based on their technical capacity
- Good accessibility to site ensured that there was no hindrance in movement of materials and equipments to site
- High quality Techno-Economic Feasibility Report and Detailed Project Report infused confidence in lenders because of which the process of funding was an easy affair
- Drawings was released in time which meant that contractors need not had to wait for the same
- Scope of work was defined very precisely giving no room for changes/ modifications at a later date
- Evaluation process of bids were done in a transparent manner
- There was proper dispute resolution mechanism which meant that project was not halted because of disputes between the parties
- Contract was enforced in letter and spirit
- Afforestation was done in and around the plant to take care of environmental problems subsequent to construction of project
- As there was a consensus on construction of this project between the various political parties, political risk was minimised
- Concerned stakeholders were taken into confidence prior to commencement of project
- Pre-bid meeting with contractors minimised the apprehensions of the contractors regarding the project to a very great extent
- Timely release of mobilisation funds enabled the contractors to mobilise the resources to the site well in advance of commencement of project
- Agreement with contractors on variations/ deviations arising subsequently out of execution of contract minimised the contractual risks considerably.
- There was a three tier planning and monitoring system which ensured that the cost performance index and schedule performance index at any point of time did not exceed the limits
- Design of all major structures was carried out by an experienced team who had indepth understanding of the subject
- Proper technical investigations were carried out and action was taken accordingly to strengthen the soil bearing capacity
- Frequent checking of quality of materials/ construction infused confidence in the quality of the work that was executed.
- For foreseen and unforeseen risks, proper insurance was taken to mitigate the impact in the event of occurrence of any risk
- Insistence on usage of Personal Protective Equipment by workers enhanced safety aspects at site and thus chances of accidents was almost nil but for minor incidents.
- Proper supervision by the top management and contractor side during the erection of boiler/turbine/ generator ensured that there was no mishaps at site

- Continuous follow up regarding milestone of each activity
- Preparation of proper manuals/checklists for erection and commissioning
- Dedicated project team for each of the functional areas
- Insuring of materials at site against theft/ pilferage which indemnified the contractor in the event of loss of materials at site
- Emergency Diesel Generator (DG) facility in the event of failure of supply and one standby DG set was provided so that work was not hampered.
- Use of flyash bricks which preserved the environment and conserved top soil
- Proper work permit system was in place and strictly followed

CONCLUSION

This project highlights one of the best risk management practices that was adopted in the construction of any infrastructure project in India and because of effective project management, the project was completed substantially ahead of schedule and at 10% lesser than the projected cost. Hence, it can be concluded that risk management plays a vital role for a project to be successful.

Sustainable Alternative to External Curing: Use of Superabsorbent Polymer in Concrete

Jyoti P Bhusari, Akhilesh A More

Department of Civil Engineering, Sinhgad College of Engineering, Pune, Maharashtra

✉ jpbhusari.scoe@sinhgad.edu

ABSTRACT

External water curing is one of the traditional and conventional method used for curing the concrete at site which uses substantial amount of water. In the scenario of paucity of water, the new alternative to curing is use of Super Absorbent Polymers (SAP) that can absorb large amount of liquid and swell substantially to form a soft and insoluble gel. The property of SAP to absorb water and release the water when required makes it ideal material for internal curing agent. SAP promotes autogenous healing by releasing the absorbed water during hydration process and thereby is helpful to control autogenous shrinkage of concrete at early age. This provides a new alternative way to control early age cracking of concrete. This paper presents the results of the extensive experimentation carried out to assess the potential use of super absorbent polymer to mitigate early age shrinkage cracking and its use as an internal curing agent. This is done by conducting water absorption test, sorptivity test, early age shrinkage cracking test and mechanical tests viz; compression, split tensile and four-point bending tests. For the experimental program, specimens of M30 grade of concrete is considered with 0%, 0.5%, 1% & 1.5% of superabsorbent polymer by weight of cementitious material in concrete. Two sets of specimens are cast for mechanical tests viz; air cured and water cured. The experimental results for compressive, split tensile and flexural strength of concrete showed super absorbent polymer up to 1% dosages in concrete is most effective in both air and water curing. Its use in air cured condition has maintained the designed strength whereas its strength has increased by 65% in water cured condition as compared to strength of controlled specimen. Early age shrinkage cracking test results showed the concrete cracking area highly reduced when super absorbent polymer with 1% dose as an internal curing agent was used in concrete. With this dosage of SAP, the time of occurrence of initial surface crack of concrete was delayed by more than 10 hours as compared to controlled specimen and area of the cracks was very minimal as compared to controlled specimen.

Keywords : Super absorbent polymer; Autogenous healing; Internal curing agent; Shrinkage.

INTRODUCTION

Curing insures proper hydration of cement thereby insures achievement of the desired strength and durability of concrete. Proper curing helps to reduce shrinkage. In high strength concrete, where the water cement ratio is kept very less, plastic shrinkage, drying shrinkage and thermal cracks can occur in concrete. There is also a higher risk of autogenous shrinkage at the early stage, when the concrete is still unmaturing [9, 17]. Internal curing (IC) of concrete is one of the remedial measures to this problem. IC helps for hydration process in concrete which maximize its potential in a simple, economical and sustainable way. IC till now is done using pre-wet expanded shale, clay and lightweight aggregate. Now, researchers have come up with a new material called as super absorbent polymer (SAP) as an internal curing agent which exploits its property to absorb large amount of water, sustain it during mixing process and make it available during the hydration process [6,18]. It is made from lightly cross-linked and partially neutralized poly acrylic acid and available in powdered and gel form. The abilities of SAP is to absorb and retain large volumes of water and aqueous solutions. They can swell to a rubbery gel form when immersed in water [10]. This property of SAP can very well be exploited in concrete technology by considering the application of SAP as an internal curing agent [7, 8]. Didier Snoeck et al., used a cross-linked potassium salt polyacrylate which showed a substantial effect on the water permeability of cracked specimens of concrete as the overall permeability was reduced by a factor 104. The smaller copolymer of acrylamide and sodium acrylate proves not to be efficient to seal a crack, mainly due to its size. The small size of sodium acrylate is inappropriate for total sealing of the cracks as they are not able to bridge a crack effectively and are possibly washed out [7]. B J Olawuyi et al. observed the absorption capacity of SAP in both water and cement pore solution to increase as the time of immersion increases [4, 21]. Addition of SAP in concrete increases the compressive strength, flexural and tensile strength as compared with the conventional concrete [3, 20].

This paper tries to assess the potential use of SAP to mitigate early age shrinkage cracking and hence its use as an internal curing agent. The absorption properties of SAP are studied beforehand. The effect of SAP on various mechanical properties of concrete is studied by conducting compressive, split tensile and flexural strength tests on concrete performed for two curing conditions viz; air cured and water cured condition. Water absorption test and sorptivity test on concrete are conducted to understand the absorption characteristics of SAP. Early age shrinkage cracking test is performed to understand the potential of SAP to mitigate early age shrinkage cracks in concrete.

MATERIAL PROPERTIES AND MIX DESIGN

The properties of the materials used in the experimental program and mix design of the concrete used are as follows.

Materials

Materials conforming to IS 12269:2013 [13] was used throughout the work. Specific gravity of cement was 3.15. Locally available fine aggregate and coarse aggregate conforming to IS 383-1970 [11] specifications are used. The specific gravity of both the aggregate is 2.81. Water absorption and fineness modulus of fine aggregate was 1.023 % and 4.26 respectively. Coarse aggregate of size 20 mm and less is used. Water absorption and fineness modulus of coarse aggregate was 0.2% and 5.94 respectively. The water used was potable, colorless and odourless that is free from organic impurities of any type. Super plasticizer Auramix 400 conforming to the specifications IS 9103:1999 [12] is used to improve workability of concrete. Potassium polyacrylate based super absorbent polymer in powdered form was used.

Mix Design

Mix design is carried out for M30 grade of concrete using IS 10262:2009 [14]. The mix proportion of 1:2.24:2.86 with water cement ratio of 0.44 is used. The Super absorbent polymer in the dosage of 0.5%, 1% and 1.5% by weight of cementitious materials is used along with appropriate dosage of super plasticizer to maintain the desired workability (slump value of 70-80 mm). Two sets of specimens are casted for mechanical tests viz; air cured and water cured. The experimental tests for compressive, split tensile and flexural strength of concrete are carried for variation in SAP dosages. The compressive strength is found at the end of 7-,14- and 28- days whereas other tests are conducted at the end of 28- days.

TESTING METHODS

Water Absorption Test on Super Absorbent Polymer

Water absorption test on super absorbent polymer is conducted using a specimen in a cylindrical plastic mould of 100 mm diameter. The mould is supported by means of two metallic rods as shown in **Fig. 1**. The empty weight of whole assembly is taken as initial reading W_1 . Super absorbent polymer in powdered form having weight 2 gm (W_2) is spread evenly at the bottom of the cylinder which is formed using plastic net is having very fine mesh. Now the assembly is placed over a bath of water in a tray in such a way that the bottom of mould immerses by 1 mm from the free surface of water.

Weight of whole assembly is taken after 5 minutes, 30 minutes and 1 hour as the SAP absorbs the water and designated as W_3 .

The water level in the tray was constantly maintained by replenishing the water absorbed by SAP.

Total water absorbed by SAP will be $W_3 - W_2 - W_1$ (gms)

Fig 1. Experimental setup for water absorption test on super absorbent polymer

Water Absorption Test on Concrete

The absorption test conforming to ASTM 642-06 [2] was conducted on specimens cast in 150 x 150 x 150 mm cubical moulds. The specimens were water cured specimens for 28_days with variation in SAP dosages.

Sorptivity Test:

The sorptivity test is conducted as per the specifications laid down in ASTM 1585 [1]. The schematic diagram for sorptivity test and actual test set up is as shown in Fig. 2 & Fig. 3.

Fig. 2. Schematic of test procedure [1]

Fig. 3. Setup for sorptivity test

The specimens with 100 mm diameter and 50 mm length are preconditioned to 80% relative humidity and 50°C temperature in humidity-controlled chamber for 4 days and then kept in a sealed container for at least 15 days. The sides of the concrete sample are sealed. The initial mass of the sample has taken and specimens are immersed to a depth of 1-3 mm in the water. Readings in terms of gain in mass are noted at required time intervals. The gain in mass per unit area over the density of water is plotted versus the square root of the elapsed time. The slope of the line of the best fit of these points is reported as the sorptivity.

Early Age Shrinkage Cracking Test:

The test is based on the China Structural Building Society standard CCES 01[5], which has suggested flat panel test technique for testing the crack resistance of concrete. The size of mould used in this test for a slab specimen is 600 mm × 600 mm × 63 mm. The side plates of the mould are welded with 10 mm diameter rods protruding for length of 100 mm. Total 14 rods are provided on each face in two layers in staggered fashion as shown in Fig.4. This facilitates the concrete to be restrained enabling the process for restrained shrinkage.

The fresh concrete is poured in flat-panel mould and is kept in environmental chamber (Refer Fig. 5) where the temperature is maintained at 30±2°C and the relative humidity is maintained at 60%. The wind speed of 4.5 m/s blowing over the concrete surface is maintained by providing a fan in the chamber. Concrete surface is observed at every 30 minutes interval. Once the 1st surface crack is visible the observations are then taken at an interval of 1 hour. The number of cracks, crack length, initial cracking time and crack width are recorded for a period of 24 hours. The development of cracks on concrete specimen are drawn progressively as cracks developed and the crack area is found out using equation as follows:

$$S = \left(\frac{1}{2N} \sum_i^N W_i L_i \right) \frac{N}{A} \tag{1}$$

where,

W_i = maximum width of the i^{th} crack (mm);

L_i = length of the i^{th} crack (mm);

N = total number of cracks;

A = surface area of the slab (m^2).

Fig. 4. Slab specimen for restrained shrinkage test

Fig. 5. Setup for environmental chamber

Fig. 6. Concrete specimen for early age shrinkage cracking test

Compression Strength Test

Compression test performed on 150 x 150 x 150 mm cubical specimens as per IS: 516–1959 [15]. 7, 14- and 28-day compressive strength is found.

Tensile Strength Test

This test is carried out on cylinder of size 150 mm diameter and 300 mm height as per IS: 5816-1999 [16].

Flexural Strength Test

The two point flexural test is conducted on the beam specimen of size 150 x 150 x 700 mm conforming to IS: 516–1959 [15].

RESULTS AND DISCUSSIONS

Water Absorption Test on Super Absorbent Polymer

Water absorption test carried on 2 grams of superabsorbent polymer and result is recorded at the end of 5 min, 30 min and 1 hour. Results of absorption test showed that 85% of water is absorbed by SAP in just 5 minutes as compared to its full absorption capacity. After 30 minutes 98% of full absorption capacity was achieved. Full absorption condition is achieved in an hour. The weight of the sample did not increase thereafter. The results show that SAP is able to absorb water 331 times its original weight.

Water Absorption Test on Concrete

As per the results of the water absorption test on concrete as shown in **Fig 7**, it is observed that there is increase in the water absorption with increase in amount of super absorbent polymers in concrete.

Fig. 7. Water absorption of concrete for different dosages of SAP

Controlled specimen absorbed 5.62% of water by the weight of specimen. For specimens with 0.5%, 1% and 1.5% of SAP absorbed 5.83%, 6.23% and 6.30% of water by the weight of specimens. This increase is not so significant because the average increase of water absorption is hardly 0.4%.

Sorptivity Test

The results of sorptivity test is represented by the graph shown in **Fig. 8** which shows plot of the water absorbed by the specimens vs. square root of time. The rate of absorption of water given by slope of the curve is obtain in two parts to get initial (up to 6 hrs. of experiment) and secondary (after 6th to 8th day of experiment) rate of absorption, which are represented in **Fig. 9 and Fig.10** respectively for different dosages of SAP.

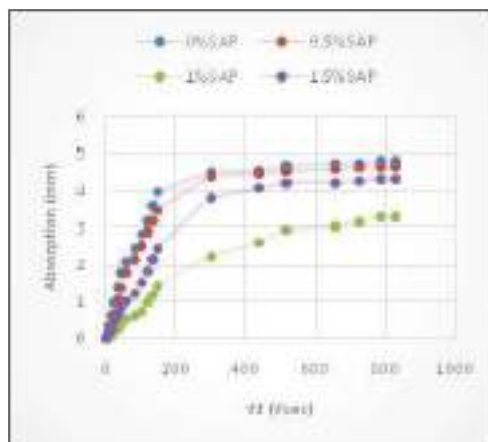

Fig. 8. Water absorption vs square root of time for sorptivity test

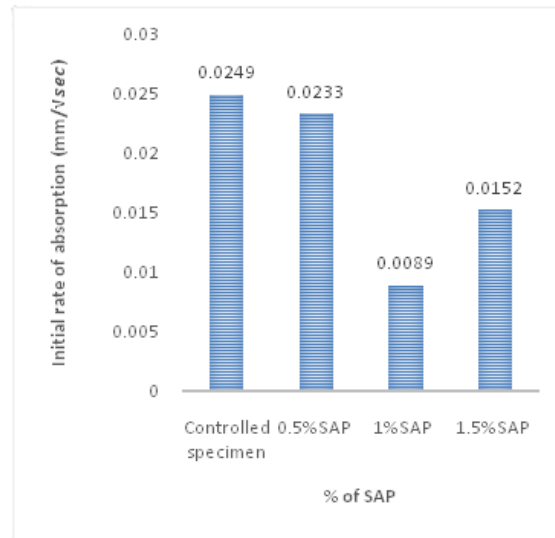

Fig. 9. Initial rate of absorption for different dosages of SAP

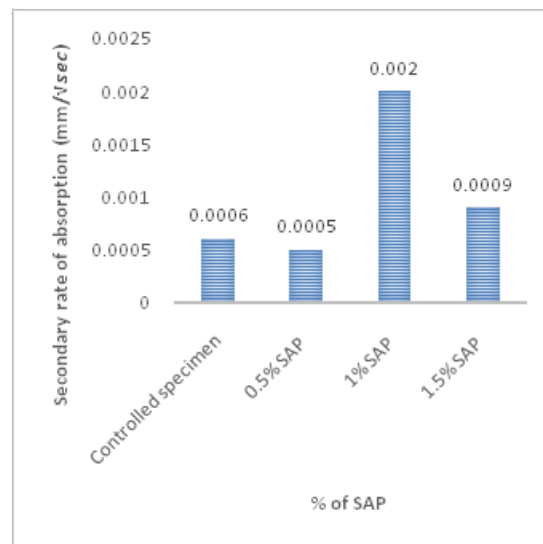

Fig. 10. Final rate of absorption for different dosages of SAP

With increase in amount of SAP from 0% to 1%, the value of initial rate of absorption is reduced. The minimum value is observed for 1% addition of SAP i.e. 0.0089 mm/√sec which increases to 0.0152 mm/√sec for 1.5% addition of SAP. The maximum value of secondary rate of absorption observed for 1% of SAP i.e. 0.002 mm/√sec and for controlled specimen and specimen with 0.5% SAP it is observed to have nearly same values i.e. 0.006 and 0.005 mm/√sec respectively.

Early Age Shrinkage Cracking Test

In this test, the initial cracking time, crack width, crack length, the final number of cracks, and the cracking area of specimens at 24 hours were recorded and given in **Table 1**. The average wind speed was 4 m/s. The temperature and relative humidity conditions were respectively 35 °C and 26%. The control specimen shows the first crack at 45 min, which is much earlier than the specimens with SAP. The amount and the length of cracks as well as the cracking area decreased significantly for the specimens with SAP as compared to the controlled specimen. Control specimen had 35 cracks with cracking area of 147170 mm²/m². For specimen with 1% of SAP only four cracks could be found. The number of cracks decreased by 88.59% and the cracking area decreased greatly to 0.15 mm²/m² in case of 1% SAP. When the SAP dosage was increased from 1% to 1.5%, the initial cracking time was decreased by 90 min. Also, the crack width for 1.5% SAP specimen was wider than that of the 1%

SAP specimen. The measured cracking area decreased with the increase of SAP dosage except in the 1.5% SAP specimen. This suggests that SAP dosage of 1% can be considered as suitable dosage. When this amount is exceeded, the additional SAP as internal curing agent does not help to mitigate the shrinkage cracking of concrete. This is because when the SAP dosage exceeds what the concrete needs, it leaves excessive water and capillary voids in the hardened concrete that reduces the tensile strength.

Table 1. Observations of early age shrinkage cracking test

% SAP	Time in which First crack appeared (mins)	Ave Crack width (mm)	Crack length (mm)	Number of cracks	Cracking Area (mm ² /m ²)
0	45	0.5	1730	35	147170
0.5	630	0.2	195	7	2.65
1	870	0.1	68	4	0.15
1.5	780	0.1	79	6	0.40

Compressive Strength Test

The test results of 7_day, 14_day and 28_day compressive strength for controlled specimen and air cured specimens with 0%, 0.5%, 1% and 1.5% of SAP content in **Fig. 11** and corresponding results for water cured specimens are given in **Fig. 13**.

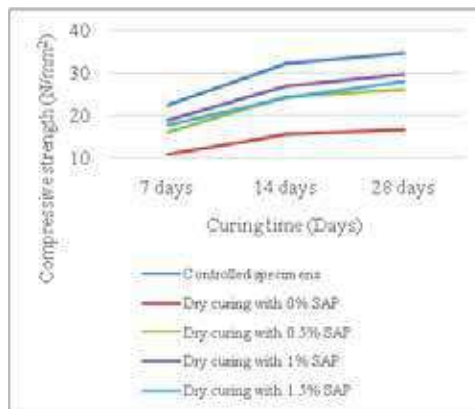

Fig. 11. Compressive strength vs curing days graph of controlled specimens with dry air cured specimens of varied SAP contents

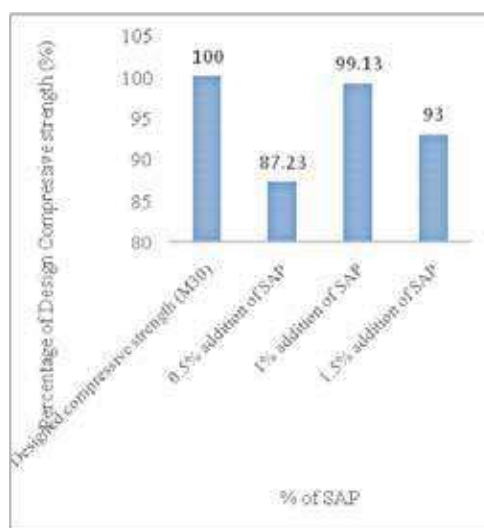

Fig. 12. Achieved compressive strength for air cured specimens by addition of various dosages of SAP to design strength

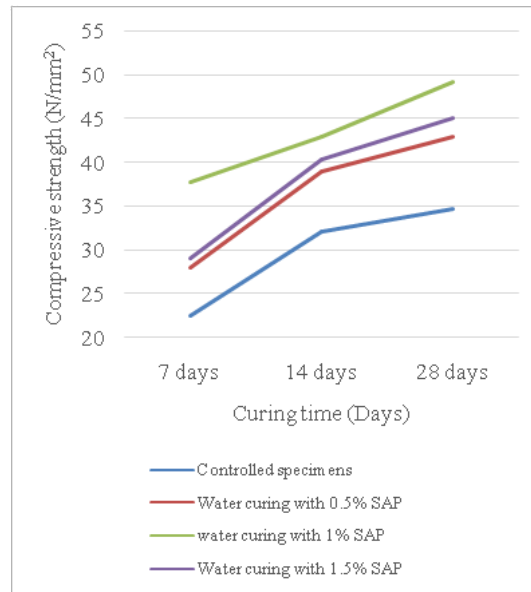

Fig. 13. Compressive strength vs curing days graph of controlled specimens with water cured specimens of varied SAP contents

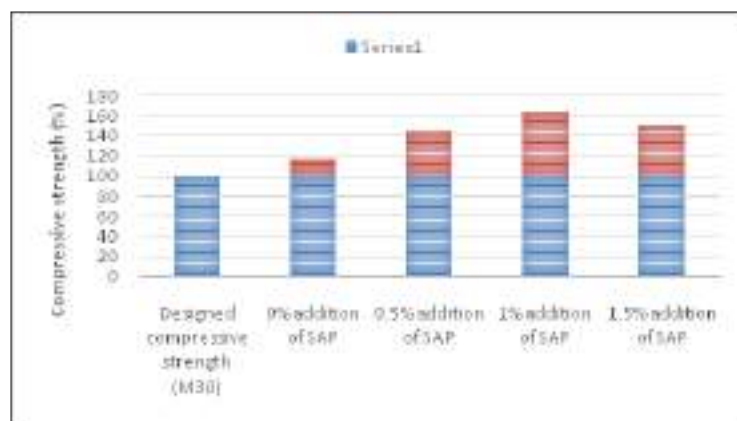

Fig. 14. Additional compressive strength for water cured specimens by addition of various dosages of SAP to design strength

50% reduction in compressive strength of air cured specimen with 0% SAP is observed when compared to controlled specimens (water cured). Increase in strength for air cured specimens with addition of super absorbent polymer in concrete is observed. The specimens with 0.5% and 1% addition of SAP in concrete has achieved by about 87.23% and 99.13% respectively of design compressive strength. Specimens with 1.5% addition of SAP in concrete achieved 93% design strength. These observations are shown in **Fig. 12**. In case of 1.5% addition of SAP, strength is reduced due to formation of excessive voids in concrete. Dosage of 1% addition of SAP in concrete proves to be suitable again.

The compressive strength of water cured specimens for 28 days with 0.5% and 1% addition of SAP in concrete has increased by about 43.1% and 64% respectively of design compressive strength. In case of specimens with 1.5% addition of SAP in concrete the compressive strength increased by only 50.4% of design strength which is again proves the suitable dosage of SAP as 1%. (**Refer Fig. 14**).

Flexural Strength Test

Flexural strength for different dosages of SAP with air cured specimens and water cured specimens is recorded and plotted in **Fig. 15** and **Fig. 16** respectively. Reduction of 31% flexural strength of air cured specimens at the end of 28 days as compared to controlled specimens (water cured) is observed. The air cured specimens with 0.5% and 1% addition of SAP in concrete has

achieved by about 85.71% and 100% flexural strength as compared to controlled specimen. The flexural strength of water cured specimens with 0.5% and 1% addition of SAP in concrete has increased by about 28.07% and 63.3% respectively as compared with the controlled specimens as shown in Fig. 16.

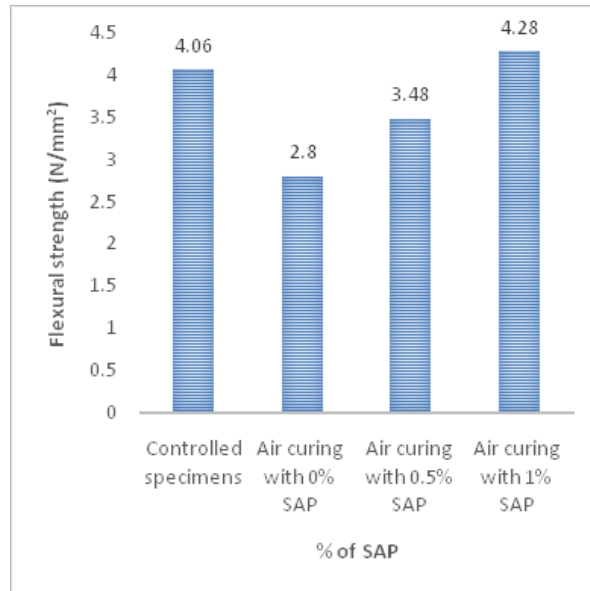

Fig. 15. Flexural strength for different dosages of SAP with air cured specimens

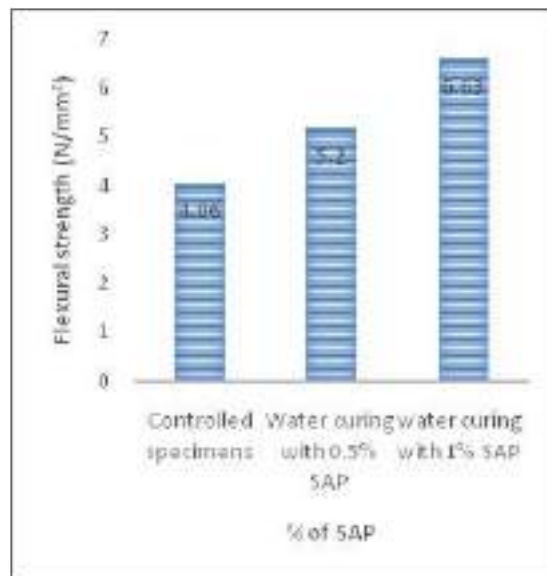

Fig. 16. Flexural strength for different dosages of SAP with water cured specimens

Split Tensile Strength Test

Split tensile strength for different dosages of SAP with air cured specimens and water cured specimens is recorded and plotted in Fig. 17 and Fig. 18 respectively. It is observed that almost 59% of reduction in split tensile strength of air cured specimens for 28 days with 0% SAP takes place when compared to controlled specimens i.e. water cured for 28 days.

The air cured specimens with 0.5% and 1% addition of SAP in concrete achieved about 43.29% and 75.77% split tensile strength of controlled specimen. The tensile strength of water cured specimens for 28 days with 0.5% and 1% addition of SAP in concrete has increased by about 19.32% and 51.8% split tensile strength of controlled specimens respectively.

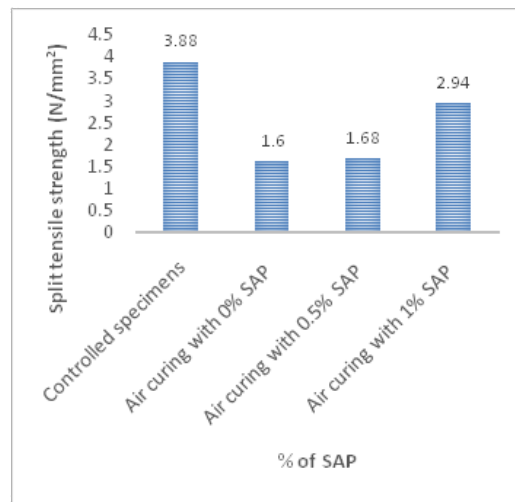

Fig. 17. Split tensile strength for different dosages of SAP with air cured specimens

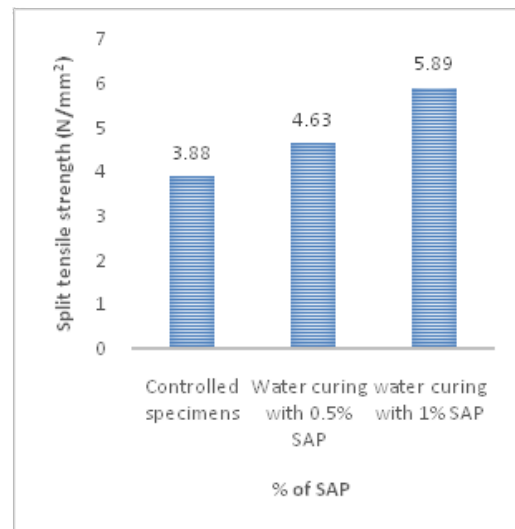

Fig. 18. Split tensile strength for different dosages of SAP with water cured specimens

CONCLUSIONS

Various tests were carried out on super absorbent polymer to verify its properties and on concrete with different dosage of super absorbent polymers to study its effect on mechanical properties such as compressive strength, tensile strength and flexural strength as well as shrinkage test along with durability tests such as water absorption test and sorptivity test. The conclusions made from the interpretation of the test results are given as follows:

- 1) It is observed from the water absorption test on SAP that full absorption capacity of super absorbent polymer is achieved within an hour. It is observed that weight of water absorbed by SAP is about 330 times the weight of SAP.
- 2) Controlled specimen of concrete absorbed 5.62% of water by the weight of specimen. The specimens with 0.5%, 1% and 1.5% of SAP absorbed 5.83%, 6.23% and 6.30% of water by the weight of specimens which is just 0.4% more. Thus, it is observed that increase in amount of super absorbent polymers in concrete does not increase water absorption capacity significantly.
- 3) The air cured specimens with 0.5% and 1% addition of SAP in concrete has achieved by about 85% and 99% respectively of design compressive strength. Specimens with 1.5% addition of SAP in concrete achieved 93% design strength which is slightly reduced as compared to 1% addition of SAP.

Super absorbent polymer as an internal curing agent promotes self-curing in concrete, hence the strength is maintained, but as the proportion of the SAP increases, the proportions of voids generated in concrete after the water in SAP is used increases and hence there is decreasing trend in compressive strength.

- 4) The compressive strength of water cured specimens for 28 days with 0.5% and 1% addition of SAP in concrete has increased by about 45% and 65% respectively of design compressive strength.
- 5) The air cured specimens with 0.5% and 1% addition of SAP in concrete has achieved by about 85% and 100% flexural strength as compared to controlled specimen. The flexural strength of water cured specimens for 28 days with 0.5% and 1% addition of SAP in concrete has increased by about 30% and 65% respectively as compared to flexural strength of controlled specimens.
- 6) The air cured specimens with 0.5% and 1% addition of SAP in concrete has achieved by about 50% and 75% split tensile strength as compared to controlled specimen. The split tensile strength of water cured specimens for 28 days with 0.5% and 1% addition of SAP in concrete has increased by about 20% and 50% respectively flexural strength of controlled specimens.
- 7) The initial rate of absorption for controlled specimen observed, has much higher value i.e. $0.0249 \text{ mm}/\sqrt{\text{sec}}$ than specimens with SAP. As increase in amount of SAP from 0% to 1% the value of initial rate of absorption reduced. The minimum value of initial rate of absorption observed for 1% addition of SAP i.e. $0.0089 \text{ mm}/\sqrt{\text{sec}}$. For 1.5% addition of SAP value of initial rate of absorption slightly increased to $0.0152 \text{ mm}/\sqrt{\text{sec}}$. On the other hand, maximum value of secondary rate of absorption observed for 1% of SAP i.e. $0.002 \text{ mm}/\sqrt{\text{sec}}$. The value of secondary rate of absorption for controlled specimen and specimen with 0.5% SAP observed nearly same values i.e. 0.006 and $0.005 \text{ mm}/\sqrt{\text{sec}}$ respectively. It is observed that water ingress in controlled specimen is highest in case of initial rate of absorption. But for secondary rate of absorption, water ingress is highest for specimen with addition of 1% SAP which is nearly similar to results of water absorption of concrete.
- 8) The concrete cracking area was highly reduced when super absorbent polymer as an internal curing agent was used in concrete up to dosage of 1%. With a dosage of SAP up to 1% the time of occurrence of initial surface crack of concrete was delayed by more than 10 hours as compared to controlled specimen.

Thus, SAP has a potential use in concrete as an internal curing agent and it is a sustainable alternative to external curing which can save substantial amount of water. Its inclusion in concrete improves the performance of concrete against early age shrinkage phenomenon. It also improves the mechanical properties of concrete if used as an admixture in normal concrete.

A Case Study on Stabilized Shallow Foundation for a Large Oil Storage Steel Tank on Soft Soil

Somdev Pakrashi

Managing Partner, Consultants Engineers & Builders (Geotechnical Engineering Consultancy Firm), Kolkata

✉ s_pakrashi@rediffmail.com

ABSTRACT

Soft clayey subsoil was encountered at shallow depths, during geotechnical investigation, at the site for one large diameter oil storage steel tank in Singur, Hooghly, West Bengal, India. Bearing pressure from the tank was observed to be greater than the net safe bearing capacity of the subsoil below traditional sand pad. A usual solution by piled sand pad foundation construction was not considered first the same being costly and time consuming. Instead, a number of trial analyses were taken up considering compacted coarse sand layer of different thickness by replacing the existing soft sub soil below the sand pad to check if a suitable thickness of compacted coarse sand course could achieve necessary ground improvement to increase bearing capacity of the stabilized soil along with required reduction of net bearing pressure and settlement values, below stabilized sand course, to provide a safe stabilized foundation base at shallow depth for the large storage steel tank. Thus, by utilizing the use of a stabilized shallow foundation base, a safe and economic foundation system could be achieved for the large oil storage steel tank on soft soil.

Keywords : Stabilization; Sand pad; Oil storage steel tank; Net bearing pressure; Differential settlement; Soft soil.

INTRODUCTION

A geotechnical investigation work in respect of foundation for one 32m dia. x 15m ht. tar oil storage tank was taken up in Mahishtickry, Singur, Hooghly. Subsoil profile up to(-) 1.7m (layer 1) was a locally compact fill of soft silty clay, in general. It was followed by soft to medium silty clay becoming stiff at places, at lower reaches, upto (-) 6.25m overlying a 1.25m thick stratum of loose to moderately dense silty fine sand. Bearing pressure from the large tank was too high to consider a suitable foundation base at shallow depths containing soft clayey soil. Usually such foundation problems can be solved by a piled foundation or piled raft foundation system. But a shallow sand pad foundation on improved ground in the form of a compacted coarse sand layer of required thickness by replacing existing soft soil is a cheaper and less time consuming solution if it can provide adequate factor of safety against shear and settlement failures. Different case studies in connection with large storage steel tanks on soft soil have also concluded that ground improvement has the most appropriate potential to provide a solution to a foundation problem for storage steel tanks. Nowadays, a large number of tank foundations have been treated with different ground improvement techniques and many such cases have been presented in journals or conference publications [1, 2, 3, 4] was thought, therefore, necessary, to try to utilize the concept of stabilization of the foundation base with the use of compacted coarse sand in layers by replacing existing poor subsoil up to the required shallow depth. A considerable number of references made it clear, as well, that stability and settlement are two major aspects to design a safe shallow oil storage steel tank foundation [5,6]. In reality, uniform settlement does not pose dangerous problems. Differential settlement, which is the vertical difference of two points at the foundation structure interface, initiates distress of the tank foundation, if it is excessive, and may lead to complete tank rupture [7, 8]. Differential settlement occurs due to non-homogeneity and compressibility of the subsurface deposit as well as non-uniform distribution of load on to the foundation base. This paper presents the use of ground improvement by filling and compaction of coarse sand by replacing soft soils at shallow depth leading to the increase in bearing capacity of the foundation base along with control of differential settlement for stability and prevention of damage of the tank structure components. Analyses were made to find out the required thickness of the stabilized course of sand as foundation base and finally a safe and economic stabilized shallow foundation system for the tank was achieved.

OBJECTIVE OF THE STUDY

It has been observed that although a piled foundation is the usual solution for a safe foundation system for large oil storage steel tanks on weak soils, a necessary consideration for a cheaper solution, where ever possible, should be made in the form of stabilized shallow foundation system where compacted layers of coarse sand replacing the existing poor subsoil to the required

depth below ground level may provide a safe shallow foundation base. A safe stabilized shallow sand pad foundation base would save a lot of construction cost and time, in comparison to the same required for a piled sand pad foundation. This paper focuses on sharing the experience of such an economic solution in terms of ground improvement for a large oil storage tank foundation on soft soil and brings about the lead for the subject of the study.

ASSUMPTIONS

- i. Evaluation for settlements, loads on the foundation base, effect of foundation load on the next stratum etc. have all been carried out according to the provisions of applicable clauses of IS8009-1,1976 , IS1892,1979, IS 6403,1981, IS1904,1986, as well as other relevant books and codes of practice.
- ii. Soil Investigation & testing works at site and laboratory have all been conducted following the provisions of applicable clauses of SP 36-1,1987, SP 36-2,1988 and other relevant IS codes.
- iii. Centre of gravity of excavation and the installed structure coincide.

STUDY AREA AND SUB SOIL PROFILE

The site that was earmarked for the 32 m Dia. x 15m ht. tar oil storage tank at Mahishticky, Singur, Hooghly, West Bengal was found to be a flat terrain. Subsoil profile as obtained by necessary site investigation and laboratory tests, contains the following layers:

Layer	Range	Thickness (m)	Description
1	0.0 -1.70	1.70	Locally compacted fill having silty clay mixed with sand and some brick pieces followed by silty fine sand, at places, at lower reaches. N=3-6, G = 2.69-2.71 Least c =2.86 t/m ² , Av.mv = 0.0024 m ² /t 10 – 20 t/m ² .
2	1.70 - 6.25	4.55	Soft to medium silty clay being clayey silt at places. N= 4 - 5, G =2.7 - 2.71 Least c = 3.29t/m ² , Av.mv= 0.00185m ² /t 10 – 20 t/m ²
3	6.25 -7.50	1.25	Loose silty fine sand mixed with little clay, at places. N=4 - 8, G=2.69 c= nil, φ = 29.5o - 30.5o, mv = nil, sc = nil
4	7.50-24.75	17.25	Medium to stiff silty clay becoming very stiff clayey silt/silty clay with kankar at lower reaches. N=7 – 26, G =2.7 -2.72 Av. c = 7.60 t/m ² , Av.mv = 0.0009m ² /t 2.5 -5 t/m ²
5	24.75 – 48	23.75	Very stiff to hard clayey silt to silty clay. The layer contains some sand and kankar mixed with clay, at places, at lower reaches-up to termination depth. Av. c =15.3 t/m ² , G =2.7-2.72 N=30 - 66, Av mv= 0.00022m ² /t 0.0 - 2.5 t/m ²

DISCUSSION

It is usual to provide a sand pad below oil storage steel tanks in order to raise the bottom plate to a desired level above the existing ground surface to prevent corrosion of steel plates by accumulation of surface or subsoil water around the tanks .The sand pad also provides resilience to the surface and transfers the load without causing local stress concentration at the tank bottom and allows the plates to move radially or circumferentially with varying conditions of temperature and stress [9].Thickness of the sand pad, above ground surface, had already been fixed by the client as 0.9m. Considering 0.5 m thick excavation and removal of top soil for usual preparation of base for the sand pad, total thickness of sand layer below tank bottom including sand pad works out to (0.9+0.5) m =1.4m and depth of foundation becomes 0.5m below ground level. It was observed from necessary analysis that net bearing pressure at 0.5m, below usual sand pad, worked out to 14.77 t/m² and ultimate bearing capacity of layer 1, ranging from ground level up to a maximum depth of (-) 1.7m, was 19.17 t/m². Obviously, F.S. =

$19.17/14.77 = 1.30$ was less than allowable limits i.e. 1.7 [10]. Therefore, a shallow foundation base at (-) 0.5m in layer 1 is not suitable for the large storage tank. Piled foundations are usually provided to prevent large differential settlements in very poor subsoil conditions [9]. Therefore, solution to the foundation problem could be safely achieved by piled foundation system to transfer the oncoming load from the large tank bottom to layer 4 having stiff to hard silty clay. But it is an expensive and time consuming affair. It is also essential to achieve economy in construction in respect of oil storage tanks for depots and other purposes as those are usually provided in large numbers on any given site [9]. In the present case, therefore, it was considered first to study the results applying ground improvement technique and check whether the large oil storage tank could be safely placed on a shallow stabilized base. Stabilization of soil by mechanical process has been in practice for hundreds of years. It results in improving the density of soil along with its other related engineering properties like settlement, cohesion, internal friction etc.[10]. Compaction is a major type to bring about soil stabilization the process requiring, in general, a heavy weight to drop repeatedly to compact the soil at optimum moisture content. This is usually the cheapest method of improving site soils [10]. In the present case vibratory portable compactor of required capacity was used to compact coarse sand in 0.15m layers at optimum moisture content after excavation and removal of soft soils up to the required depth below ground level (Fig. 2). A number of necessary trial analyses were carried out using different thickness of compacted sand course in replacement of the soft subsoil below ground level to check if a possible solution can be achieved in the form of a shallow stabilized foundation. It was finally observed that the net bearing pressure below a stabilized/compacted sand base at (-)2.1m worked out to 12.43 t/m^2 and ultimate bearing capacity of layer 2 (from (-)1.70m to (-) 6.25m) was 22.23 t/m^2 . Therefore, F.S. achieved = $22.23/12.43 = 1.79$ which was more than allowable limits [10]. It was also clear from settlement calculations that necessary settlement parameters were below allowable limits. It was thus observed that soil stabilization by excavation and removal of existing sub soil below ground level and replacing the same with 2.1m thick coarse sand free from dirt or fine sand compacted in 0.15m layers at optimum moisture content could provide a safe shallow sand pad foundation base for the large dia. oil storage steel tank providing adequate factor of safety. Compaction in confined condition according to necessary procedures as well as checks to ascertain required density, quality and standard of compaction were also adhered to in order to achieve best results.

Fig. 2. Stabilized foundation base for the oil storage steel tank

CONCLUSIONS

Large oil storage steel tanks transferring heavy load pose problems in respect of a safe shallow foundation system especially on soft soil. In such cases a piled sand pad foundation is considered to transfer the heavy load safely on to a sufficiently strong stratum at deeper depth although it is a costly and time consuming affair. Present study in respect of a large dia. heavily loaded oil storage steel tank shares the experience where stabilization of foundation in the form of compacted coarse sand in replacement of existing poor soil up to required depth was taken up and it was observed that compacted coarse sand layer of required thickness could adequately improve the foundation base for the large steel storage tank in i) providing adequate factor of safety against shear failure and in ii) reducing necessary settlement values below allowable limits. As a result a safe shallow stabilized sand pad foundation system for the large oil storage steel tank could be used successfully. Utilization of the concept of soil stabilization by replacing the existing soft subsoil with compacted coarse sand of required thickness and density can thus be very effective and beneficial, wherever possible, to provide a safe shallow sand pad foundation base for large oil storage steel tanks on soft subsoil as it negates the use of a piled sand pad foundation system and consequently saves a lot of construction cost and time.

APPENDIX

Calculations

Bearing Capacity

I. Check for a safe shallow foundation base at (-) 0.5m : Consider a shallow foundation when the tank bottom is on $(0.9\text{m} + 0.5\text{m}) = 1.4\text{m}$ thick compact sand course placed at 0.5m below ground level (**Fig. 1**).

Bearing pressure at tank bottom, considering hydrostatic test = $15 \times 1 + 360 \times 4 / [\pi \times (32)^2] = 15.45 \text{ t/m}^2$. Considering 45° spread of load, bearing pressure at (-) 0.50m .

i) Load from the tank and its content = $15.45 \times 322 / (32 + 2 \times 1.4)^2 = 13.06 \text{ t/m}^2$

ii) Load from 0.90m thick sand pad = $0.9 \times 2 \times 40^2 / \{40 + 2 \times 0.5\}^2 = 1.71 \text{ t/m}^2$

Total = 14.77 t/m^2

Ultimate bearing capacity, qultat (-)0.50m, = $cN_c s_c d_c i_c [11] = 2.86 \times 5.14 \times 1.3 \times 1.0029 \times 1 = 19.17 \text{ t.m}^2$ F.S = $19.17 / 14.77 = 1.3 < 1.7$. Not o.k.

Least $c = 2.86 \text{ t/m}^2$, $s_c = 1.3$, $\gamma_{\text{sand}} = 2 \text{ t/m}^2$ $d_f = 0.5\text{m}$, $N_c = 5.14$ $d_c = 1 + 0.2 \times d_f / B = 1 + 0.2 \times 0.5 / 34.8 = 1.0029$, Self wt. of tank = 360 ton, Permissible F.S = 1.7 [10]

II. Check for a safe shallow sand pad foundation on 2.1m thick stabilized base (**Fig. 3**).

Fig. 3. Load transfer from the oil storage tank to virgin soil at (-) 0.5m

Bearing pressure at tank bottom, considering hydrostatic test = 15.45 t/m^2 .

Considering 45° spread of load, net bearing pressure at 2.1m below G.L.:

i) Load from tank and its content = $15.45 \times 32^2 / \{(32 + 2 \times (0.9 + 2.1))\}^2 = 10.956 \text{ t/m}^2$

ii) Load from 0.90m thick sand pad = $0.9 \times 2 \times 40^2 / (40 + 2 \times 2.1)^2 = 1.474 \text{ t/m}^2$

Total = 12.43 t/m²

q_{ult} at (-) 2.1m = 3.29 x 5.14 x 1.3 x 1.011 x 1 = 22.226 t/m²

F.S = 22.23/12.43 = 1.79 > 1.7, Hence o.k.

Least c = 3.29t/m², $s_c = 1.3$, $i_c = 1$, $d_f = 2.1m$, $\gamma_{sand} = 2t/m^2$, $d_c = 1 + 0.2 \times 2.1 / 38 = 1.011$

Settlement

I. Immediate Settlement

q_n = Bearing pressure at tank bottom considering hydrostatic test, = 15.45 t/m²

$E_{weighted\ av.} = \sum H_i E_i / \sum H_i$ [10] = (3 x 5670 + 4.15 x 1975 + 1.25 x 1230 + 17.25 x 4950 + 23.25 x 9950) / 48 = 343468.75/48.9 (Fig. 5) ≈ 7024 t/m²

Immediate settlement = $S_i = q_n \cdot B (1-\mu^2) \times I_o / E_{weighted\ av.} = 15.45 \times 32 \times (1-0.322) \times 1 / 7024 = 0.063$ m

B = 32m, $q_n = 15.45t/m^2$, $I_o = 1$, $\mu = 0.32$, $E_1 = 5670t/m^2$, $E_2 = 1975$ t/m², $E_3 = 1230$ t/m², $E_4 = 4950$ t/m², $E_5 = 9950$ t/m²,

$H_1 = 3m$, $H_2 = 4.15m$, $H_3 = 1.25m$, $H_4 = 17.25m$, $H_5 = 23.25m$

II. Consolidation settlement

Consolidation settlement has been considered from (-)2.1m in layer 2 as m_v and s_c are nil or negligible in coarse sand.

Considering 45° spread of load, s_c = Consolidation settlement=

$\sum H_i m_{vi} \Delta p_i = 4.15 \times 0.00185 \times 10.10 + 0 + 17.25 \times 0.00091 \times 4.11 + 23.25 \times 0.00022 \times 1.58$ (Fig.5) = 0.15m

$H_1 = 3m$, $H_2 = 4.15m$, $H_4 = 17.25m$, $H_5 = 23.25m$,

$Av.m_{v2} = 0.00185m^2/t$, $Av.m_{v4} = 0.00091m^2/t$, $Av.m_{v5} = 0.00022m^2/t$, $\Delta p_2 = 10.10t/m^2$, $\Delta p_4 = 4.11t/m^2$, $\Delta p_5 = 1.58t/m^2$, $d_f = 2.1m$, $D = 2R$ where R=Radius

After pore pressure and Fox's correction [9], S_c corrected = 0.8 x 0.97 x 0.15m = 0.1164m

Calculated total settlement = 0.063 + 0.1164 = 0.1794m. This quantity is less than even allowable average settlement for large tanks i.e., 0.18m [12] and average settlement is always considerably less than total settlement. Hence, o.k

Now, maximum differential settlement = 50% of total settlement [9] = 0.5 x 0.1794m = 0.0897m

According to Klepikov, 1989[12], allowable differential settlement = 0.004D = 0.004 x 32m = 0.128m > 0.0897m Hence, o.k.

Again, according to API 653, 1998[13], allowable differential settlement, 0.031R = 0.031 x 16 = 0.496m > 0.0897m. Hence, o.k.

Fig. 4. Load transfer from the oil storage tank to layer 2 below 2.1m thick compacted coarse sand layer

Fig. 5. 2.1 m thick stabilized course underlain by subsoil layers up to (-) 48m

Theoretical Calculation of Crack Width in Pile for Tension and Lateral Loading

Md Arshad Jamal, Vaishali Sharma, Deepak Singh, Ayan Khan

Department of Structural Design, Quality Austria Central Asia, New Delhi

✉ jamal@qacamail.com; ✉ vaishali@qacamail.com

ABSTRACT

The cracks likely to initiate on a tension and lateral loaded pile and would causes greater tension load and deflection at the pile head however, there is lack of investigation on the cracking response due to tension and lateral loaded piles. In this article, a full scale calculation of crack width on circular pile shaft under tension and lateral load is done. Although the explicit calculation of flexural crack width in rectangular section of beam and slab can be found widely in varies textbooks. A design and calculation procedure for a circular section crack width calculation in tension and lateral load have not been documented.

Keywords : Tension; Lateral loaded; Pile; Crack width.

INTRODUCTION

When pile foundation is design for GBT (Ground Base Tower) or GBM (Ground Base Monopole) tower, tension and lateral load act on it. That's why it is required to check the permissible tension stress limit in bars and the crack width due to tension and lateral loading. Deep foundation design for GBT or GBM in tension and lateral load is predominantly in design prospective. Tension and lateral loads develop the cracks in pile shaft. Generally deep foundation is design wherever water table is below 1.0m from ground level or soil bearing capacity is very low. Because pile in water table, cracks in pile shaft is harmful for the reinforcement of pile shaft.

According to the IS456:2000 in the member where cracking in the tensile zone is harmful either because they are exposed to the effects of the weather or continuously exposed to moisture or in contact with soil or ground water, an upper limit of 0.2mm is suggested for the maximum width of cracks. Cracking due to direct tension is of serious concern than flexural cracking, it cause a clear separation in the concrete through the entire section of the member. At the crack location, the reinforcement is required to resist the entire tension and the width and spacing of cracks are governed primarily by the reinforcement detailing. If minimum percentage of reinforcement is provided then steel may yield and result in wide crack width. However, crack width can be significantly controlled by maintaining number of bars in circular cross section with relatively low tensile stress and strain in the steel at service loads. As in the case of eccentric tension the concrete in between the cracks resists some tension (tension stiffening effects). The axial stiffness of the member can be greatly reduced by the presence of wide cracks but this reduction is mitigated by the tension stiffening effects. The Indian Standard code does not have any recommendation to calculate crack width of the member subjected to direct or eccentric tension. However, such recommendation is given in the British code BS8110. BS8110 permits the extension of the procedure prescribed for crack width prediction under pure flexure to situation of flexural to situation of flexural combined with axial tension. When axial tension is predominates, the entire section is likely to be under tension with the neutral axis lying outside the section. This is the extreme case of pure tension, here $X \rightarrow -\infty$. It is suggested that if f sufficient to consider $x = -D$

Fig. 1. Pile shaft section and x is the neutral axis

PROPOSED METHOD OF CALCULATION

Assuming pile of diameter D, tension load on pile is T, and moment acted on pile due to the lateral load is M.

Fig. 2. Pile shaft action of tension and moment

According to **Fig. 2** , S is the center to center spacing between the main longitudinal reinforcement, Cmin is the minimum clear cover, r is the radius of camber of main reinforcement, ϕ is the radius of main reinforcement, ϕ_{tr} is the radius of secondary reinforcement, n is the number of longitudinal reinforcement, acr is the diagonal distance to main longitudinal reinforcement and outer edge of concrete surface (the calculation point of crack width), b is the width of the section at the longitudinal reinforcement level, a' is the distance between outer most surface to the crack calculating point and d is the effective depth of the section.

Radius of camber of main reinforcement

$$r = \frac{(D - 2C_{min} - 2\phi_{tr} - \phi)}{2}$$

Spacing of main reinforcement

$$S = 2r \sin\left(\frac{\pi}{n}\right)$$

Effective cover

$$d_c = \frac{D}{2} - r \cos\left(\frac{\pi}{n}\right)$$

Shortest distance between main longitudinal reinforcement and at calculation point of crack width

$$a_{cr} = \sqrt{\left(\frac{S}{2}\right)^2 + d_c^2} - \left(2\phi_{tr} - \frac{\phi}{2}\right)$$

Crack width in any section depends on the stress distributed on the longitudinal main bars, Indian standard code permit the limit of stress in main longitudinal bars (at cracked location) is $0.8f_y$, where f_y is the yield stress of main longitudinal reinforcement.

The average steel strain ϵ_m may be calculated on the basis of basic of following assumption.

The concrete and steel are both consider to be fully elastic in tension and compression. The elastic modulus of the steel may be taken as 200kN/mm^2 . Whereas, elastic modulus of the concrete is as derived by the equation

$$E_s = 5000\sqrt{f_{ck}}$$

The code allow to an approximation for computing ϵ_m which involves only conventional ‘cracked’ section analysis using modular ratio concept.

$$\epsilon_m = \epsilon_1 - \epsilon_2$$

These assumption are illustrated in Fig. 3.

Fig. 3. Location of NA

Whereby x (depth of neutral axis) and the ‘apparent’ strain ϵ_1 at the extreme fiber of concrete is calculated. Assuming the tensile strength of concrete is zero.

$$\epsilon_1 = \frac{f_{st} a' - x}{E_s d - x}$$

The strain ϵ_2 corresponds to a reduction in tensile stress in reinforcement suggest a reduction in tensile force in reinforcement, equal to the force generated by the triangular distribution of tensile stress in concrete.

$$\epsilon_2 = \frac{b(D-x)(a'-x)}{3EA_s(d-x)}$$

If the value of calculated value of ϵ_2 is exceed by ϵ_1 (ie $\epsilon_m < 0$) then it should be constructed that the section is uncracked.

Calculation of ϵ_1 and ϵ_2 for circular section as below.

$$f_{st} = f_{st1} + f_{st2}$$

Where f_{st1} is tensile stress in steel in outer most steel and f_{st1}, f_{st2} is stress due to axial and moment in section respectively, A_{st} is the total area of reinforcement

$$f_{st1} = \frac{T}{A_{st}}$$

$$M = f_{st2} \cdot A_{st} \cdot y' + f_{st2}'' \cdot A_{st}'' \cdot y'' + f_{st2}''' \cdot A_{st}''' \cdot y''' + f_{st2}'''' \cdot A_{st}'''' \cdot y'''' + \dots$$

Where f_{st2} is the stress in outer most reinforcement due to bending moment.

$$f_{st2}' = f_{st2}$$

$$y' = x + \frac{D}{2} + r \cos \frac{\pi}{n}$$

$$y'' = x + \frac{D}{2} + r \cos \frac{3\pi}{2n}$$

$$y''' = x + \frac{D}{2} - r \cos \frac{3\pi}{2n}$$

$$y'''' = x + \frac{D}{2} - r \cos \frac{\pi}{n}$$

Stress in reinforcement at different level

$$f_{st2} = \frac{f_{st2}}{y'} y''$$

$$f_{st2} = \frac{f_{st2}}{y'} y'''$$

The expression for predicting crack width.

$$w_{cr} = \frac{3a_{cr}\epsilon_m}{1 + \frac{2(a_{cr} - C_{min})}{(D - x)}}$$

PROPOSED METHOD OF CALCULATION

After analytical calculation of crack width, we observed that value of x and f_{st2} is depend on each other, where the location of neutral axis is outside the section and if neutral axis is more far from the section then the stress in reinforcement due to bending in minimum. Although according to BS code BS 8110 Part 2, for cases where the whole section is in tension, an effective value of neutral axis can be estimated by interpolation between the following limiting conditions:

- a) where the neutral axis is at the least compressed face,
- b) for axial tension, Neutral axis location = -D

But if we calculate by the conventional section analysis method , then we found the neutral axis location is between the compressed face and depth of the section.

Some numerical example are solved and observed the variation with the parameter as graph given below, and the factors Influencing crack-widths as mentioned below.

- Tensile stress in the steel bars;
- Thickness of concrete cover;
- Diameter and spacing of bars;
- Depth of member and location of neutral axis; and
- Bond strength and tensile strength of concrete.

Crack width varies with diameter of pile

The variation of crack width with the diameter of pile, and in calculation acting tensile load, moment is constant, but the number of reinforcement is same and the diameter of bars is varies, for the study of the crack width.

Where ,

Tu= 100kN and Mu= 25kNm

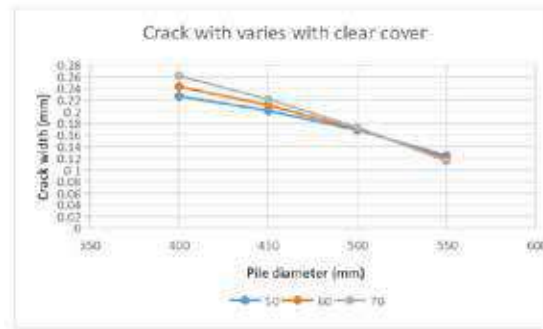

Graph 1. Crack width with varies with diameter of pile

Crack width varies with clear cover in pile shaft

The variation of crack width with the clear cover in pile shaft, and in calculation acting tensile load, moment, number of reinforcement, diameter of reinforcement is constant for the study of the crack width.

Where, $T_u = 100\text{kN}$ and $M_u = 25\text{kNm}$, Reinforcement is $16\phi-8\text{No's}$

CONCLUSION

Crack width in pile shaft is minimize with increasing the diameter of pile shaft, but when diameter of main reinforcement is increases then the value of crack width also increases. Crack width also increases with the increasing of clear cover.

ABSTRACT

Structural Health Monitoring (SHM) has gained a lot of importance in today's scenario. Significant reduction in the cost of sensors and connectivity, made remote data collection possible to monitor the structures and perform critical analysis so that actions can be taken to assess and enhance the residual life of the structures. Internet of Things (IoT) is the network of smart sensors that combines sensing and transmission of various responses of the structures to distant servers which continuously processes and monitors these responses. The present paper proposes an integrated platform of IoT for damage detection using Wi-Fi module, Raspberry Pi, (Piezoelectric) PZT sensors along with Digital to Analog (DAC) and Analog to Digital converters (ADC). Signatures are extracted from PZT sensors and an algorithm is proposed to identify and quantify the damage comparing with base line signatures of healthy structural component. The algorithm is executed using python. In the present work, tests are conducted on simply supported aluminium beam surface bonded with two PZT transducers, one acts as an actuator and the other acts as a sensor. Beam is actuated by a sinusoidal vibration through a python program. DAC converts this digital wave into analog form and sends it to actuator which excites the aluminium beam. Initially signatures from healthy beam are recorded for a specified time duration. The sensor receives the response from aluminium beam which is in analog form and this response is converted to digital form using ADC. Damage is induced in the form of crack in aluminium beam signatures data is collected from piezoelectric sensor and communicated to Raspberry Pi. An algorithm is proposed to quantify the damage using cross correlation (CC).

Keywords: SHM; IoT; Raspberry Pi; Cross correlation index; PZT.

INTRODUCTION

From the past few years, there have been many advancements in various fields using the Internet of Things (IoT). Many innovative ways are proposed to make human life easier especially in the fields of electronics, industrial machines, aircraft, etc. Structural Health Monitoring (SHM) is one process where IoT is yet to be used for the real-time purpose. SHM is a process of detecting incipient damages in a structure, with the help of sensors and data acquisition systems, we can monitor uninterruptedly to detect and estimate the residual life of the structure. Sensors are more sensitive and accurate than any other equipment used for health monitoring. They play a significant role in capturing responses and sending continuous data from the host structure. IoT in SHM comes into the picture when we want to store this huge data into a wifi module or cloud. IoT also helps to monitor any type of structure remotely without human inspection at the structures. It helps to analyze the responses using various signal processing techniques and mathematical models.

The present project aims on detecting the extent of damage on a smart aluminium beam using PZT transducers and Raspberry Pi. Two PZT transducers are surface mounted on aluminium beam where one acts as an actuator while the other is a sensor. Harmonic analysis is done by inducing sinusoidal excitation into the beam. PZT sensor receives these responses and sends them to thingspeak which is a cloud platform for storing data.

LITERATURE REVIEW

Although SHM using sensors is applied to various fields, very few works were done on Structural Health Monitoring using the Internet of Things (IoT). Scantly available journal papers mainly include crack detection of various specimens with the help of different sensors using Raspberry Pi. Carmelo Scuro et al. [1] have used the acoustic emission technique to monitor reinforcements in structural components. Ultrasonic waves are generated and received through the emitter and receiver. In case any damage is detected in the structural reinforcement, an alert message is sent to the server through remote control and

service room. Alex Myers et al. [2] have used ABAQUS software to generate guided longitudinal waves on steel plate. They have proposed a mathematical model to find the size and location of the damage. Md Anam Mahmud et al. [3,4] have proposed a signal processing technique on aluminium sheet. Two PZT transducers are mounted on aluminium sheet and the output of these transducers is stored in oscilloscope. The output data is further analyzed using MATLAB where a simple cross correlation index is used and to remove noises from extracted data, Butterworth filter is used.

Ahmed Abdelgawad and Kumar Yelamarthi [5] have conducted both experimental and analytical studies on steel plate to find damage location and size. The results of both studies are compared and percentage error is calculated. In [6], NRF module and Pro-Trinket microcontroller are used to send data to Raspeberry Pi. Hongyang Zhang et al. [7] have conducted SHM using IoT to remove environmental effects from the data obtained from the sensor, principal component analysis is conducted. After removing the environmental effects, Hilbert Huang Transformation (HHT) is used for signal analysis. Amira Zrelli et al. [8] have proposed IoT based SHM to detect the location of damage using wireless sensor network. “Mean Normalized Curvature Difference of Waveform Jerk Energy” (MCDWJE) and “Curvature Difference Probability waveform Jerk” (CDPWJE) methods are used to detect damage in bridges. Byung Wan Jo et al. [9] have combined IoT with blockchain technology to monitor underground structures. In [10], Lin-sheng Huo et al. have done damage detection based on Cross Correlation Function Amplitude (CCFA) and Support Vector Machine (SVM). This consist of two stages, in the first stage, data is extracted from the sensors using CCFA from dynamic responses of the host structure and in the second stage, this data is sent to SVM to classify the damage of the structure. Seunghee Park et al. [11] have proposed instantaneous baseline signatures using Digital Signal Processing (DSP) module where the damages are detected based on Wavelet Transform (WT) and Cross Correlation (CC) index. Shao-Fei Jiang et al. [12] have proposed Fuzzy Neural Networks (FNN) and data fusion techniques for detecting the damage in structures. These methods are useful when the output data is vast and inaccurate. Victor Giurgiutiu and Giola Santoni-Bottai [13] have used piezoelectric wafer sensors for monitoring composite structures from that of the metallic structures. F.Lamonaca et al. [14] have used MQTT protocol to avoid the waiting time of the receiving signal. They have shown the importance of synchronization of signals. Apoorva Jindal and Mingyan Liu [15] have shown the significance of network computing using wireless sensor networks. The present work aims at identifying and quantifying the damage in smart beams using PZT Transducers.

EXPERIMENTAL STUDY

Methodology

As the actuator excites the host structure with a sinusoidal wave, while receiving the response from the sensor, noises are observed. To remove these noises caused by environmental effects or external vibrations, the Butterworth filter is used. The CC value is calculated for the excitation signal and the filtered signal. The CC value obtained is 0.971.

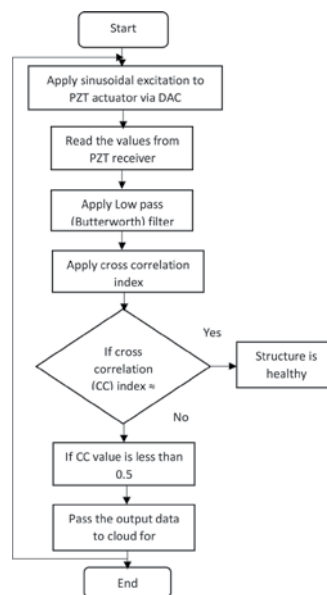

Fig. 1. Flow chart of proposed SHM

Hardware Required

The proposed IoT experimental work consists of Raspberry Pi, Analog to Digital converter (ADC), Digital to Analog converter (DAC), PZT, breadboard and jumper wires. Breadboard is used for temporary connections where soldering is not required. Jumper wires are used for connecting Raspberry Pi to PZT transducers via DAC and ADC.

Raspberry pi 4. Raspberry Pi 4 Model B is the new generation of Raspberry Pi single board computer which supports more RAM (2GB). It is a 64bit quad core ARM-Cortex A72 with a clock speed of 1.5GHz. With the help of the New Out of Box software (NOOBS), operating system of Raspberry Pi (Raspbian) is installed. It contains 5V and 3.3V GPIO pins and the current it draws is around 3.4 watts. It is used to send the excitation signal, store the receiving data, analyze the data, and send the data to the cloud.

DAC. As the PZT transducers accept only analog signals, we use a digital to analog converter (DAC) to send the sinusoidal wave to the actuator. MCP4725 is used for converting the signal into analog form. It is a 12 bit, low power, and high accuracy converter. Its power supply ranges from 2.7V to 5.5V. It has an I2C interface at a rate standard, fast and high speed with 100KHz, 400KHz, and 3.4 MHz respectively.

ADC. ADC is used for converting an analog signal received from the PZT sensor to a digital signal and send it to Raspberry Pi. In the present work, ADS1015 is used which is a 12bit resolution with a sample rate of 3.3 kSPS. Its power supply ranges from 2.0V to 5.5V. It has got four channels i.e., with one ADC we can connect up to four sensors.

Piezoelectric Transducers. When mechanical strain is induced it produces an electric field and vice versa. Therefore, it acts as both an actuator and a sensor. In the present work, two PZT transducers are surface mounted on either side of the specimen. One excites the signal and the other receives the signal.

Proposed Damage Quantification Metric

The damage is identified from the results, signatures, or responses obtained by various sensors used for monitoring the structures. The most commonly used damage metrics are the Root Mean Square Deviation (RMSD) method, Cross-Correlation (CC) method and Covariance method. In the present work, Cross-Correlation is used for identifying and determining the extent of the damage. The PZT actuator excites the host structure with a sinusoidal wave towards the sensor. The PZT sensor receives the wave and sends it to Raspberry Pi. An algorithm is proposed to compare the similarity of two signals. The CC value is used as a damage index which is defined as

$$CC = \frac{\left(\frac{1}{N}\right) \sum_{i=1}^N (E_i - \bar{E})(R_i - \bar{R})}{\sigma_E \sigma_R} \tag{1}$$

Where E and R are excitation and receiving signals respectively. A structure is said to be healthy when the excitation and receiving signals are similar whose CC value is 1. The structure is said to be damaged if the CC value is other than 1. The value of CC ranges from -1 to 1.

EXPERIMENTAL SETUP

A simply supported smart aluminium beam of 33cm length, 2.5cm width and 0.2cm thick is considered. The effective length of the beam is 30cm and the actuator and sensor are surface mounted at a distance of 10cm and 18cm respectively from the left support. Since the PZT transducers send and receive only analog data, ADC and DAC are used for converting the signals from analog to digital and vice versa. The actuator is connected to DAC (digital to analog converter) and the sensor is connected to ADC (analog to digital converter). Through a python driven program, a sinusoidal wave of 16kHz frequency is sent to the actuator via DAC towards the sensor. This actuator excites the host structure and sensor receives the signal. An algorithm is written to apply the Butterworth filter to remove noises from the received signal. A low pass filter of order 5 is used whose cutoff frequency (normalised) is 0.5. Cross correlation index is applied on the excitation signal and received filtered signal. The CC value obtained for a healthy beam after applying the Butterworth filter is 0.9714. Now, cracks are induced at increase in percentages between actuator and sensor. CC value is observed for different crack percentages and a graph is plotted to compare the damaged beam with the healthy beam.

Since the main aim of using the internet of things platform is to store the output data in the cloud, the output of CC values is sent to thingspeak in the form of graphs. These graphs are seen using a mobile app which helps us to monitor from any place.

Fig 2. Damaged specimen

Fig 3. Experimental Setup

RESULTS AND DISCUSSION

Cracks of different widths are induced in the aluminium beam and the CC value is obtained using the mathematical model in python. The values of CC are

Table 1. CC values for different crack widths

Damage percentage	0% (Healthy)	1.25%	2.5%	3.75%	5%
Cross correlation (CC) index	0.9714	0.656	0.1013	-0.6123	-0.9341

The samples of the received signals are taken for all the cases and graphs are plotted to compare with the healthy samples.

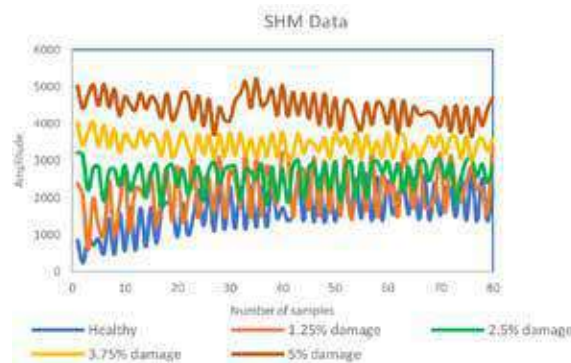

Fig 4. Variation in amplitudes at different crack widths

Fig 5. A snapshot of Thingspeak’s web page

CONCLUSION

- In this study, IoT based SHM platform is designed to detect damages (cracks) in simply supported aluminium beam.
- An algorithm is proposed to identify the damage extent using python.
- CC index values are extracted through the python program from the received signal from ADC after the application of filters.
- It is observed with the increase in the percentage of damage width, there is a decrease in CC index which varies between -1 to +1.
- The main aim of IoT is to store the data in the cloud therefore the values are stored in thingspeak and are used for further analysis.
- The CC values are viewed through a mobile application and a threshold limit is set. The mobile application gives an alarm signal whenever the CC value is reduced below 0.5.

Comparison of GSA 2003 and 2016 Guidelines for Evaluating Progressive Collapse Potential of Steel Moment Resisting Frame Building

Parthav P Patel, Digesh D Joshi

Department of Civil Engineering, Institute of Technology, Nirma University, Ahmedabad, Gujarat

✉ 19mcl13@nirmauni.ac.in

ABSTRACT

Progressive collapse is a situation in which failure of primary load bearing element leads to failure of adjoining members progressively which is disproportionate to initial event. In this paper, progressive collapse potential of 9-storey steel moment resisting frame building is evaluated using Alternate Load Path Method (APM) as specified in GSA 2003 and 2016 guidelines. Analysis results obtained from linear static, non-linear static and non-linear dynamic analysis are compared for middle column removal scenario from longitudinal bay. Demand Capacity Ratio (DCR) for beams and columns located adjacent to removed column are determined from linear static analysis. Load carrying capacity of building is found out using non-linear static analysis. Displacement time history is plotted at the location of removed column from non-linear dynamic analysis. Also, ductility demand and plastic hinge rotations obtained from non-linear analysis following GSA 2003 and 2016 guidelines are compared. From the analysis, it is observed that if structure is designed following to GSA 2003 guidelines then its vulnerability against progressive collapse will be higher compared to design following to GSA 2016 guidelines.

Keywords: Progressive collapse; Steel building; Alternate load path method; Demand capacity ratio; Displacement time history.

INTRODUCTION

Progressive Collapse due to loss or failure of local load carrying element which leads to partial or total collapse of structure. The extent of damage or collapse disproportionate to initial event. It is a dynamic failure mechanism in which loss of one or more local load carrying element propagates through a system causing widespread collapse progressively. It is caused by abnormal loads like gas explosions, vehicular impacts, blast loading etc. The design/protection of structure against progressive collapse becomes a concern after Ronan Point apartment tower collapse (London, 1968) due to gas explosion. Also, after collapse of World Trade Centre (New York 2001), many government and private agencies worked on the development of guidelines for progressive collapse resistant structure. The U. S. General Services Administration (GSA) and Department of Defense's Unified Facility Criteria (UFC) employ the Alternate Load Path Method (APM) to ensure the resistance of structure against progressive collapse. Marjanishvili [1] compared the four analytical methods – linear static, linear dynamic, non-linear static and non-linear dynamic analysis to evaluate progressive collapse potential of structure. Marjanishvili et al. [2] evaluated the progressive collapse potential of 9-storey steel building using SAP2000 following to GSA 2003 guidelines. Kim and Kim [3] assessed the progressive collapse resisting capacity of 3, 6 and 15 storey steel moment frames using GSA 2003 and DoD 2005 guidelines. Progressive collapse of 4 and 8-storey moment resisting frame was assessed by Kiakojoury et al. [4] using static and dynamic incremental analysis following to GSA 2013 guidelines. Authors concluded that static analysis predicts larger capacity compared to dynamic analysis against progressive collapse. Tavakoli and Alasthi [5] evaluated progressive collapse potential of 5 and 15 storey steel buildings under lateral loading. Authors concluded that, as number of bays and stories increase, progressive collapse potential of building increase.

In this paper, comparative study of GSA 2003 and GSA 2016 guidelines for progressive collapse is carried out by analyzing 9-storey steel moment resisting frame building. Linear static, non-linear static and non-linear dynamic analysis are carried for middle column removal scenario to evaluate the progressive collapse potential of steel building. The results obtained based on GSA 2003 and GSA 2016 guidelines are compared.

GSA GUIDELINES

The U. S. General Services Administration issued the guidelines for analyzing and evaluating the resistance of structure against progressive collapse. The guidelines are applicable to new and renovated federal buildings with the aim to reduce the potential for progressive collapse by utilizing Alternate Path Method (APM). The GSA guidelines were first published in November 2000 which primarily focused on reinforced concrete structures [6]. These guidelines were updated in June 2003 in order to address the progressive collapse potential of steel frame structure also. After thorough research on the available guidelines for progressive collapse, certain inconsistencies were identified and revised guidelines were published on October 2013 with 1st revision in January 2016.

Table 1. Comparison of GSA 2003 and GSA 2016 guidelines

Parameter	GSA 2003 Guidelines	GSA 2016 Guidelines
Type of approach	Threat Independent	Threat Dependent in conjunction with Interagency Security Committee (ISC)
Type of member end action	No differentiation	Force Controlled and Deformation Controlled
Preferred Analysis Methods	Linear Static (LS), Linear Dynamic (LD), Non-linear Static (NS), Non-linear Dynamic (ND)	
Load combination for LSA	2 (DL + 0.25LL)	$\Omega_L(1.2DL + 0.5LL)$ Where, Ω_L depends on governing m-factor
Load Combination for NSA		$\Omega_N(1.2DL + 0.5LL)$ Where, Ω_N depends on yield and allowable plastic hinge rotation
Load combination for LDA and NDA	(DL + 0.25LL)	(1.2DL + 0.5LL)
Irregular building analysis	DCR \leq 1.5 for linear analysis	DCR \leq 2 for LSA DCR $>$ 2 – LSA not allowed
Acceptance criteria for LSA	DCR \leq 2, for beam-flexure DCR \leq 1, for column	DCR \leq Governing m-factor for beam-flexure DCR \leq 1 for column

So, it is important to identify the major differences between these guidelines. The GSA 2016 guidelines were developed with the aim to reduce the inconsistencies between the GSA and Department of Defense (DoD) methodologies [7]. **Table 1** shows the comparison of GSA 2003 and GSA 2016 guidelines.

METHODOLOGY

The 9-storey steel moment resisting frame building is considered for the study. The beams, columns are designed as per IS 800: 2007 [8] composite slab is designed as per IS 11384: 1985 [9]. The progressive collapse potential of the building is evaluated using GSA 2003 and GSA 2016 guidelines for middle column removal scenario from ground floor and results obtained are compared. For modelling and progressive collapse analysis, SAP2000 software is used.

Description of Model

The 9-storey steel building considered for study has 6-bays in longitudinal direction and 3 bays in transverse direction [2]. The uniform spacing of column is 8.25 m in longitudinal direction and 9.75 m in transverse direction. The typical storey height is 4.3 m. The plan and elevation view is shown in **Fig. 1** and **Fig. 2**. All the beam column connections assumed as fully restrained and support condition of column to ground is considered as fix.

Loading on Building

There are total four load cases considered in SAP2000 which includes dead load, slab load, live load, and wall load. The dead load case includes the self-weight of beams and columns. The thickness of composite concrete slab is considered as 90 mm. Slab load is applied as an area load by considering density of concrete as 25 kN/m³. The live load is considered as 1.9 kN/m² on

all floors. The wall load is considered as 19.7 kN/m and applied on perimeter beams except on roof. The seismic load applied on building as per IS 1893:2016 [10] by considering building in zone III. The designed section of primary beam and secondary beam is ISMB500 and ISMB450 for all floors. Column section is designed as built-up column with 550 mm depth, 400 mm flange width, 30 mm flange thickness and 25 mm web thickness.

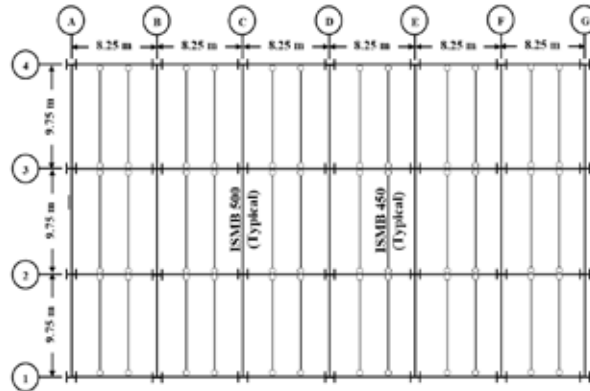

Fig. 1. Plan view of building [2]

Fig. 2. Elevation view of building

LINEAR STATIC ANALYSIS

The Linear Static Analysis (LSA) is performed to evaluate the progressive collapse potential of the building. This analysis gives an indication whether the building is vulnerable to progressive collapse or not by calculating Demand Capacity Ratio (DCR). The load combination for LSA is given in **Table 1**. As per GSA 2003 guidelines, the load increase factor is considered as 2 but as per GSA 2016 guidelines, load increase factor is depends on force-controlled and deformation-controlled action. For present study, the moment and shear in beam is classified as deformation and force-controlled respectively.

For column, moment can be force-controlled or deformation-controlled which depends on ratio of P/P_{CL} . If $P/P_{CL} > 0.5$ then moment and axial force is considered as force-controlled action, but for $P/P_{CL} \leq 0.5$, moment is considered as deformation controlled action and axial force is considered as force-controlled. P_{CL} is lower bound axial compressive strength of column.

Determination of Load Increase Factor

In GSA 2016, the different load increase factors are given for force controlled (Ω_{LF}) and deformation-controlled actions (Ω_{LD}). For force-controlled action, the Ω_{LF} is considered as 2 and for deformation controlled action Ω_{LD} is determined as per equation (1).

$$\Omega_{LD} = 0.9m_{LF} + 1.1 \quad (1)$$

Where m_{LF} is smallest of ‘m’ for any primary beam or girder which is denoted as ‘m-factor’ or ‘Demand Modifier’. Demand modifier need to find out for steel component as well as for connections and the smallest value of m is considered as m_{LF} . The m-factor for flexure in beam is depends on ratio of flange width to twice flange thickness and depth of web of beam to thickness of web. GSA 2016 guidelines suggests Table 9-4 of ASCE 41-13 to find m-factor for beam and for connections for Collapse Prevention (CP) criteria [11]. But for certain type of connections, the Table 10 of GSA 2016 should be used. For ISMB 500 beam, the value of Ω_{LD} is estimated as 3.8.

Calculation of Demand Capacity Ratio (DCR)

From linear static analysis, Demand Capacity Ratios of members adjacent to removed column are calculated. DCR for beam is calculated by considering bending moment. The axial force and bending moment are used to calculate DCR in column.

DCR for Flexure in Beam

It is the ratio of actual moment (M_{actual}) to plastic moment capacity (M_p) of the section. Mathematical expression for DCR for beam is given in equation (2).

$$DCR \text{ (Beam-Flexure)} = M_{actual} / M_p \quad (2)$$

Where $M_p = Z_p f_y$

Z_p = Plastic section modulus

f_y = Yield stress of the material

DCR for Column

There are certain equations given in ASCE 41-13 to calculate the DCR for column. The type of equation used is depends upon ratio of P/P_{CL} . P_{CL} is the lower bound axial compressive strength of column. P is the axial force acting on the column after application of increased gravity load. If GSA 2016 guidelines used then value of ‘P’ should be taken from the model generated for deformation-controlled action. Equations (3) to equation (5) is used to calculate DCR in column [11].

$$\frac{P}{P_{CL}} > 0.5; DCR = \frac{P_{UF}}{P_{CL}} + \frac{M_x}{M_{CLx}} + \frac{M_y}{M_{CLy}} \quad (3)$$

$$0.2 \leq \frac{P}{P_{CL}} \leq 0.5; DCR = \frac{P_{UF}}{P_{CL}} + \frac{8}{9} \left[\frac{M_x}{m_x M_{CEx}} + \frac{M_y}{m_y M_{CEy}} \right] \quad (4)$$

$$\frac{P}{P_{CL}} < 0.2; DCR = \frac{P_{UF}}{2P_{CL}} + \frac{M_x}{m_x M_{CEx}} + \frac{M_y}{m_y M_{CEy}} \quad (5)$$

Where, P_{UF} = Axial compressive force on column

M_x = Bending moment in section about x-axis

M_y = Bending moment in section about y-axis

M_{CLx} = Lower bound flexural strength of the member about x-axis

M_{CLy} = Lower bound flexural strength of the member about y-axis

M_{CEx} = Expected flexural strength of member about x-axis

M_{CEy} = Expected flexural strength of member about y-axis

m_x or m_y = value of m-factor for column bending about x or y-axis respectively

In the present study, DCR calculated for flexure in beams is located between gridline C1 and E1 for all stories. DCR for column is calculated for columns located at gridline C1 and at gridline E1 for all stories. C1 means the intersection point of gridline C and gridline 1. DCR for beams and columns are calculated for GSA 2003 and GSA 2016 guidelines and results are compared. The acceptance criteria for flexure in beam is governing m-factor, which is estimated as 3. **Fig. 3** shows the comparison of DCR for column. The acceptance criteria column DCR is 1.

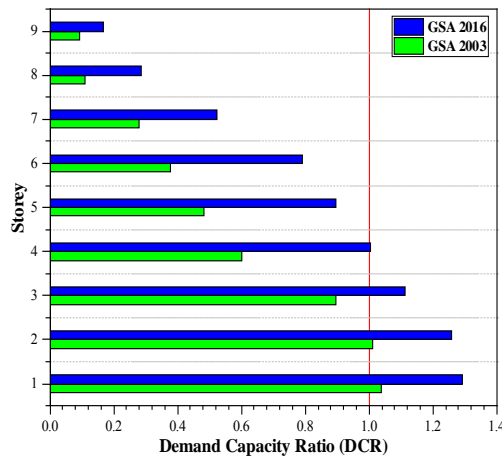

Fig. 3. DCR for Column at grid C1 or E1

From the Fig. 3, it is clear that there is a difference between the results of DCR calculated for GSA 2003 and GSA 2016 guidelines. The DCR calculated as per GSA 2016 guidelines are on a higher side than DCR calculated as per GSA 2003 guidelines.

NON-LINEAR STATIC ANALYSIS

The main advantage of non-linear static analysis is that it considers the material and geometric non-linearity. For progressive collapse it can be termed as ‘Vertical Pushover Analysis’ in which increased vertical load is applied stepwise until the structure collapses. In Table 1, the load combination is given for non-linear static analysis as per GSA 2003 and GSA 2016 guidelines. The dynamic increase factor (Ω_N) is considered as 2 as per GSA 2003 guidelines, but GSA 2016 guidelines suggest that Ω_N should be less than 2 and it’s depends on support yield rotation (θ_y) and allowable plastic rotation angle (θ_{pra}) for collapse prevention criteria. The Ω_N can be calculated from the equation (6) given below.

$$\Omega_N = 1.08 + \frac{0.76}{\left(\frac{\theta_y}{\theta_{pra}} + 0.83\right)} \tag{6}$$

The ratio θ_y/θ_{pra} is the smallest ratio for any primary element, component or connection in the model within or touching the area with increased gravity load. From, the equation (6), the Ω_N is obtained as 1.36.

The geometric non-linearity is considered in SAP200 by selecting P-delta option for non-linear static load case. To include the material non-linearity the plastic hinges are assigned in the beams and columns ends. From non-linear static analysis, the collapse load of structure can be find out.

Fig. 4. Non-linear static curve at column removal location

Fig. 4 shows that comparative graph of % of total load v/s vertical displacement for GSA 2003 and GSA 2016 guidelines. From the Fig. 4, it is evident that estimation safe load carrying by the building is different for both the guidelines. Also, the vertical displacement at column removal location is different. Table 2 shows the comparison of % of load taken by building and plastic hinge rotation between GSA 2003 and GSA 2016.

NON-LINEAR DYNAMIC ANALYSIS

Progressive collapse is highly dynamic and non-linear phenomenon. Non-linear dynamic analysis is an efficient method of progressive collapse analysis because it includes the dynamic effect along with material and geometric non-linearity. The load combination for non-linear dynamic analysis is given in Table 1. In non-linear dynamic analysis, the simulation of sudden column removal is very important. In the present study, the sudden column removal is simulated using initial conditions. Obtain the reacting force in the column to be removed from linear static analysis. Then delete the column from the model and apply the upward reacting force at column removal location obtained from equilibrium model as joint load.

Table 2. Comparison of non-linear static analysis results

Parameter	GSA 2003	GSA 2016
Total load taken by SAP	85%	99.69%
Safe Load	82%	97%
$\theta_{\text{safe load}}$ at support (from SAP)	3.74 degrees	3.86 degrees
$\theta_{\text{collapse load}}$ at support (from SAP)	5.14 degrees	5.28 degrees
$\theta_{\text{allowable}}$ (for CP criteria, ASCE 41-13)	4.97 degrees	4.97 degrees

Fig. 5. Displacement time history at column removal location

The non-linear static load case includes all gravity loads defined as an initial condition. After model reach to its equilibrium condition, the column is removed by ramping down the upward reacting force. For dynamic analysis Rayleigh damping is used with 2% damping ratio. The plot displacement time history at joint exactly above removed column is shown in Fig. 5. There is a significant difference observed between maximum dynamic displacement obtained following to GSA 2003 and 2016 guidelines. From Table 3, it is evident that the ductility demand and plastic hinge rotation is significantly higher followed to GSA 2016 guidelines compared to GSA 2003 guidelines.

CONCLUSIONS

In this study, GSA 2003 and 2016 guidelines for evaluating progressive collapse potential are compared by analyzing 9-storey moment frame building. Linear static, non-linear static and non-linear dynamic analysis are carried out for middle column removal scenario from longitudinal bay and results obtained are compared. Based on the comparative study, following conclusions are derived:

Table 3. Comparison of non-linear dynamic analysis results

Parameter	GSA 2003	GSA 2016
Ductility ($\mu = \delta_{max} / \delta_{yield}$)	168.9/61.55 = 2.74	353.5/56.96 = 6.21
$\theta_{max, support} = \tan^{-1}(\delta_{max} / \text{span of beam})$	1.17 degrees	2.45 degrees
$\theta_{max, support}$ (from SAP)	0.951 degrees	2.34 degrees
$\theta_{allowable}$ (for CP criteria, ASCE 41-13)	4.97 degrees	4.97 degrees

- The DCR for beams and columns obtained per GSA 2016 guidelines are significantly higher compared to DCR obtained as per GSA 2003 guidelines. DCR of some of the columns satisfying the acceptance criteria as per GSA 2003 guidelines but the same columns exceed the acceptance criteria as per GSA 2016 guidelines.
- The load carrying capacity of the building from non-linear static analysis is accurately identified following to GSA 2016 guidelines. Because from analysis, the almost 100% load is taken by the building safely whereas GSA 2003 guidelines estimate 82% load taken by the building. This difference occurs due to the magnitude of dynamic increase factor (Ω).
- The maximum dynamic displacement is very high followed to GSA 2016 guidelines compared to GSA 2003 guidelines. Also the ductility demand is very high when building is analyzed as per GSA 2016 guidelines compared to GSA 2003 guidelines.
- The comparison of analysis results indicates that, vulnerability of the building against progressive collapse will be high if it is designed following to GSA 2003 guidelines compared to designed following to GSA 2016 guidelines.

PSWC-BAR for Sustainable Concrete Construction

Anil K Kar

Engineering Services International, Salt Lake City, Kolkata

✉ dr.anil.kar@gmail.com

ABSTRACT

Reinforced concrete is the number one medium of construction. Such constructions with plain round bars of mild steel proved to be durable. Following the use of ribbed bars of carbon steel, concrete structures have shown signs of decay and distress early. This is due to the susceptibility of ribbed bars to excessive corrosion due to the provision and presence of ribs, and the consequent loose rust on the surface of such bars before concreting. This can not only reduce the load-carrying capacity of concrete elements, reinforced with ribbed bars, it can also lead to failures during vibratory loadings. Moreover, loose rust on the surface of ribbed bars will prevent any possible passivation of rebars, thereby hastening the process of corrosion in rebars and distress in reinforced concrete constructions. The use of PSWC-BAR, characterized by its plain surface and wave-type configuration, can not only solve the problems of excessive corrosion in rebars of high strength carbon steel and the consequent early distress in concrete structures, it makes concrete constructions sustainable by lowering the life cycle cost of constructions to a fraction of what it is today, and the adverse impact of construction on the environment and the global climate.

Keywords: Corrosion; Deformed bar; Durability of concrete Constructions; PSWC-BAR; Ribbed rebar; Reinforcing bar.

INTRODUCTION

Reinforced concrete is the most common medium of construction. Bridges, buildings, dams, stadiums, roadways and runways are all constructed with reinforced concrete.

Strength, easy formability, relatively easy availability of the component materials of construction and durability of the constructed projects have led concrete constructions to this pre-eminent position.

Reinforced concrete constructions with ribbed rebars of carbon steel (**Fig. 1**) since the mid-nineteen sixties in western countries and since the mid-nineteen seventies in India have, however, reached states of distress fairly early in life (**Fig. 2**).

Fig. 1. Fresh ribbed bars showing start of corrosion at damaged ribs

The ribbed rebars in India are required to conform to the provisions in the Indian Standard IS 1786 [1].

The worldwide problem, created by the use of ribbed bars, whether of the cold twisted deformed (CTD) or thermo mechanically treated (TMT) type, has been aptly summed up in Ref. [2] wherein it was observed : “The last two decades have seen a disconcerting increase in examples of the unsatisfactory durability of concrete structures, specially reinforced concrete ones.”

Fig. 2. Distress in staging of overhead water reservoir due to corrosion in rebars

Sixteen years later, it was remarked in Ref. [3] that “the most direct and unquestionable evidence of the last two/three decades on the service life performance of present constructions and the resulting challenge that confronts us is the alarming and unacceptable rate at which the infrastructure systems all over the world are suffering from deterioration when exposed to real environments.”

In the midst of persistent claims of tremendous advances in the manufactured materials of construction, viz., cement and rebars, a surprise was expressed in Ref. [3] thus: “What is most surprising is that this massive and horrendous infrastructure crisis has occurred in spite of the tremendous advances that have been made in our understanding of the science engineering and mechanics of materials and structures.”

There had to be reasons.

RIBS TO BLAME FOR EARLY DISTRESS IN REINFORCED CONCRETE CONSTRUCTIONS

The surprise in Ref. [3] emanated from the fact that, probably except for the writer [4] and metallurgists/engineers in Russia [5], no one wanted to see what was in front of their eyes, no one wanted to hear about it, and no one wanted to talk about it (**Fig.3**).

If they did, they would have seen all around them examples of excessive corrosion in ribbed CTD bars and ribbed TMT bars (**Fig. 1**), the use of which led to early decay and distress in reinforced concrete constructions (**Fig. 2**).

This pitiable condition of infrastructure, that has led to worldwide concern, has emanated from a failure to recognize that rebars of carbon steel, with ribs on the surface, are intrinsically susceptible to corrosion at accelerated rates.

The reasons for this intrinsic susceptibility of ribbed bars of carbon steel to corrosion at accelerated rates have been provided by in Ref. [4]. The reasons in short are :

1. residual stresses develop at the bases of ribs during the manufacture of rebars
2. cracks, which trigger corrosion, may develop at the edges of ribs at the time of manufacture, during transportation and handling (**Fig. 1**).
3. inside structures under load, nominal stresses in ribbed rebars are enhanced in keeping with the phenomenon of stress concentration due to the presence of ribs or cracks.

Fig. 3. Manufacturers, design engineers and constructors would like not to see, not to hear and not to talk about the problems inherent in high strength deformed rebars of carbon steel

4. additional stresses develop in ribs due to wedge action of such ribs against surrounding concrete
5. the sum-total of stresses and strains in 1 to 4 approach or reach yield stress or strain levels
6. rate of corrosion increases with increasing stress levels; the rate accelerates as the stress or strain approaches yield levels, and the surface becomes unstable once beyond yield, whereupon the process of corrosion becomes unstoppable
7. alkaline solution of $\text{Ca}(\text{OH})_2$ in the pores inside concrete cannot passivate the unstable steel surface at an yield state and thus cannot guard ribbed steel rebars inside concrete against corrosion
8. even without the additional stresses, which ribbed bars under service load conditions can be subjected to, the rate of both micro corrosion and macro corrosion are higher in the case of ribbed bars than in the case of plain bars
9. the rate of corrosion increases with an increase in the yield stress level of the steel material in rebars, apparently because of higher carbon contents.
10. The problem of corrosion is magnified when the strength in rebars is increased by taking recourse to cold twisting, as in the case of CTD bars, or to thermomechanical treatment, i.e., quenching as in the case of TMT bars, as it was/is done in India.
11. by the time of concreting, ribbed bars of carbon steel in many or most cases are covered with a layer of loose rust (**Fig. 4**), essentially making such bars unsuitable for use as rebars (see Subsection 5.6.1 in Ref. [7]), as decreased bond can lower load-carrying capacities [8], or even to failures, especially during vibratory loads
12. besides preventing bond between rebar and concrete, a layer of loose rust on the surface of rebars before concreting (**Fig. 4**) prevents passivation of rebars by the alkaline solution of $\text{Ca}(\text{OH})_2$ in the pores inside concrete.

Fig. 4. Ribbed bars coated with products of corrosion even before concreting, leading to a total loss of bond with concrete

SOLUTIONS

An obvious solution to the world-wide problem of early decay and distress in reinforced concrete constructions would be :

- (a) going back to the old days and use plain round bars of mild steel or use PSWC-BAR, with its plain surface and wave-type configuration, as in Ref. 4,8,9,10, 11, 12], and ordinary portland cement (OPC) of appropriate quality, or
- (b) providing surface protection systems in the nature of waterproofing [13, 14, 15, 16, 17, 18, 19], a concept that has been adopted in Subsection 8.2.1 of Ref. [21], and which is today widely used in the surface protection of concrete bridges.

PSWC-BAR FOR SUSTAINABLE CONCRETE CONSTRUCTION

References[9, 10, 11,12] offered the use of PSWC-BAR (**Fig. 5**) (initially named as C bar), in lieu of ribbed bars, whether of the CTD or TMT type or not, as a solution to the problem of early distress in reinforced concrete constructions.

In the absence of ribs or any other surface feature of any type, PSWC-BARS are free from the ill effects which bedevil today's conventional rebars of high strength steel (**Fig. 1, Fig. 2 and Fig. 4**).

PSWC-BARS are preferably hot rolled, say as in Ref.[20]. The wave pattern in a PSWC-BAR is created with the help of a pair of gear rollers at the last stand of the rolling mill process [9]. If desired, PSWC-BAR can also be cold rolled [9].

(a) typical PSWC-BARS of steel, characterized by plain surface and gentle wave-type configuration

(b) schematic view of a typical PSWC-BAR

Fig. 5. PSWC-BAR

Unlike CTD bars, PSWC-BARS are not twisted. Though PSWC-BARS are preferably hot rolled, such bars can also be quenched as in the TMT process.

For purposes of standardization, the pitch length (**Fig. 5(b)**) has been suggested to be 30 times the diameter of the rebar and the peak amplitude of deformation has been recommended to be 5 mm. Five millimeter is not a sacrosanct number. Tests on numerous concrete flexural (beam) and compression (column) elements at different universities have shown that a peak amplitude of deformation of 6 mm generally leads to better structural performances of concrete structures [8].

Tests have shown that compared to concrete elements, reinforced with conventional rebars, viz., plain, ribbed TMT and ribbed epoxy coated bars, such structures, when reinforced with PSWC-BARS, show best performances under load [9].

Besides increased load-carrying capacities, there is several fold enhancement of ductility as well as energy-absorbing capacity when flexural concrete elements are reinforced with PSWC-BARS in lieu of conventional bars [9].

Observations of rebars at site [**Fig. 1, Fig. 4, Fig. 5**] and analysis of test results have shown that there is a total misconception among engineers about “bond” between rebars and concrete, whereas in the context of reinforced concrete, “bond” is as important an element as concrete and rebars are.

In Ref. [9], three terms have been suggested, viz., bond, effective bond, and engagement to replace “bond” engineers loosely refer to.

In the case of a plain bar, it is the pure “bond”, which may be totally absent in the case of ribbed bars which, because of excessive corrosion, may be covered with a layer of loose rust (Fig. 4). In the case of ribbed bars, as in Fig. 1, there is no “bond” between such bars and the surrounding concrete, the bars are not passivated inside concrete, with attendant low life span, under-performance under static load and susceptibility to local or total structural failure under vibratory loads.

Structures with highly corroded ribbed rebars perform under load because of certain levels of “effective bond” or “engagement”.

Structural elements, reinforced with PSWC-BARS, perform the best, as because, in the absence of loose rust, the competent adherent rust on the surface of such bars aid the development of “bond”, and additionally the gentle wave-type configuration

provides additional “engagement” between rebars and concrete, leading to the best “effective bond” or “engagement” between such bars and concrete.

In the case of a PSWC-BAR, “effective bond” and “engagement” are synonymous.

With the focus on durability and thus greater sustainability of infrastructure construction, the desirable mechanical properties of PSWC-BARS have been selected as shown in **Table 1**. The reasons for the selection of the different quantities have been explained in Ref. [11], wherein it has been explained why bars of steel of 650 MPa and 700 MPa yield strength can lower the load-carrying capacities of flexural elements of reinforced concrete.

The use of PSWC-BARS as rebars can do wonders to reinforced concrete construction, and, on a long term basis to individual and national wealth, to the environment and the global climate.

BENEFITS OF USING PSWC-BARS

At no additional cost or effort, the use of PSWC-BARS, in lieu of conventional plain or ribbed bars, leads to the following benefits :

- a) several-fold longer life span of concrete structures at no added effort or cost

Sl. No.	Property	Fe 415	Fe 500	Fe 550
i)	yield stress, Min, N/mm ²	415.0	500.0	550.0
ii)	yield stress, Max, N/mm ²	500.0	600.0	660.0
iii)	Y/Y _{specified} ratio ¹	1.02 -1.2	1.02 -1.2	1.02 -1.2
iv)	TS/ Y _{specified} ratio ²	≥ 1.15 - ≤ 1.40	≥ 1.15 - ≤ 1.40	≥ 1.15 - ≤ 1.40
v)	Elongation, percent, Min. on gauge length $5.65\sqrt{A}$, where A is the cross-sectional area of the test piece	20.0	16.0	12.0

Note :

¹Y/Y_{specified} ratio refers to ratio of actual yield strength to specified yield stress of the test piece

²TS/ Y_{specified} ratio refers to ratio of tensile strength to specified yield stress of the test piece

Additional Note :

¹The steel shall be suitable for welding processes

- b) lowering the life cycle cost of reinforced concrete constructions by at least fifty percent; leading thereby to great savings in individual and national wealth.
- c) several-fold increase in ductility and energy-absorbing capacity of concrete flexural elements
- d) greater load-carrying capacities of reinforced concrete elements; with the potential to prevent catastrophes during earthquakes
- e) greater safety during earthquake events
- f) greatly diminished damages to the local and global environments
- g) greater sustainability on many counts, viz., greatly reduced life cycle cost, greater safety during earthquakes, reduced disruption to the society, greatly reduced demand on nature resources, and approximately 5% reduction in the total global emission of CO₂ from all sources.

There have been many publications in India and in the UK on PSWC-BAR since 2010. The three articles in References 10, 11 and 12 should provide an overall picture about the capabilities of PSWC-BAR.

SUMMARY

Reinforced concrete is the number one medium of construction. Besides strength, easy formability and availability of the constituent materials, trouble-free long term performance, i.e., durability of concrete structures, constructed with plain round

bars of mild steel, having yield stress of around 250 MPa to 280 MPa had helped reinforced concrete attain this position.

With time, the use of medium strength (yield stress of about 350 MPa) and high strength (yield stress of about 415 MPa and higher) adversely affected the time-dependent performance of reinforced concrete constructions, leading to worldwide concern about the poor health of infrastructure.

The use of PSWC-BAR, characterized by its plain surface and wave-type configuration, at no added effort or cost, can solve the worldwide problem of early distress in reinforced concrete construction.

Besides several-fold enhancement of life span, with many added benefits, like greatly reduced life cycle cost, the use of PSWC-BAR may prevent catastrophes during earthquakes.

In consideration of additional requirements for survivability under seismic forces, the yield stress of steel in PSWC-BAR is recommended to be limited to 550 MPa, and preferably to 500 MPa.

Recommended mechanical properties of PSWC-BAR for durable concrete constructions are provided.

The several—fold enhancement of life span of concrete structures, reinforced with the use of PSWC-BAR, can prevent staggering financial losses to individual property owners and to national economies of all countries as well as great harm to the environment and to the global climate.

Planning, Analysis and Design of G+5 Cyclone Resistant Administrative Building at Kovalam, Chennai

Amjad Latif, Shweta Devekar

Department of Civil Engineering, National Institute of Construction Management and Research, Pune

✉ Shweta.25devekar@gmail.com

ABSTRACT

The main objective of the project work is to plan, analyze and design of administrative building. The building is constructed at Kovalam, Chennai. This deals with the planning analysis and design of G+5 cyclone resistant administrative building. An attempt has been made for planning and analyzing the structure. Modelling is done for both circular and Square buildings using STAAD.PRO and AUTOCAD. The analysis of the structure with addition of lacing will be carried out using STAAD.PRO. Major design such as design of slab, design of beam, design of columns and foundation will be done. The design of cyclone evacuation shelter will be carried out using Indian standards and in accordance with National Disaster Management policies. Load calculations will be done considering dead load, live load & wind load. The necessity of the building is to provide a facility for the basic medical relief during and after disaster to safe guard basic assets needed by people to survive after disaster and to save human lives during cyclone.

Keywords: Cyclone; Shelter; (G+5); Design; STAAD.PRO.

INTRODUCTION

Instances of cyclones have been increasing in recent years owing to various reasons such as global warming and human activities. Almost every year during the period of April-May and September-December, cyclones brew in seas along Indian coastline. These cyclones are followed by strong storm surge which can enter land up to distance of 10kms. People living adjacent to coastline are most affected as storm water can stay up to several days in their homes. Further, the tidal surge accompanying the cyclone is a major cause for the loss of lives and property. It is essential to provide accommodation to the vulnerable population living along the coast during any eventuality or disaster due to natural calamities such as cyclones and associated tidal waves and storm surges. These efforts should provide robust buildings and enduring towards such calamities and should be economically viable.

Literature Review

B. S. Mashalkar et al., (2017) deals with the development of buildings and flexible structural systems which are prone to wind action. It gives effect of cyclones on various framed structures such as V, C and K which are not symmetric along both axes. In this paper two plans are taken into consideration and based on drifts results are compared for two buildings. It's found that circular building can resist maximum wind load due to the fact area exposed to wind is very less compared to rectangular and square plans. Ankush Agarwal (2013) provides information on how cyclones damages building and how the risk of loss of property and lives can be minimised. His method for construction of cyclone resistant structures is unique and leads to structural and experimental investigation & recommended protecting house by various methods like proper planning of house, use of roof truss, lacings, and vertical bracing. Jonathan Ochshorn et al (2014) Demonstrated by his work that the effect of wind on any structure will be dependent on various factors like its location and obstructions near the structure which may cause any change in air flow and the properties of the structure itself. He proved that plus shape and Non-uniform shape were the most stable shapes whereas L-shape and U-shape was the less stable of all the considered shapes. Shreyas Ashok keot (2012) Instances of cyclones have been increasing in recent years owing to various reasons such as global warming. Cyclones cannot be stopped; hence various methods are needed to reduce risk associated with it. There is a great need to make changes to buildings in present to reduce the collateral losses to these structures. Planning and design of new construction requirements for buildings are recommended to reduce the risk of structural damage in future. Dhanendra kumar et al (2015) says wind is most powerful force effecting a tall building. He presented a brief introduction to the design of different structural parts of a building to be safe in coastal areas such as roof, foundation, walls, etc. is given. In this paper various methods to alter path of cyclone are elaborated.

Thus in this study various advancement in developing a cyclone shelter are provided in most simple way and findings indicate towards effect of shape plan on drag force and wind effective pressure.

Prof. M. R. Wakchaure (2016) this paper shows the buildings having same gross area but constructed with different shapes are compared. Wind loads are determined based on gust effectiveness factor method. The critical gust loads are found. Amount of area exposed to wind in case of Circular buildings is very less, thus the wind pressure is less, square shaped buildings are less stable against wind load than circular buildings on basis of this study . Hence it is concluded that wind load is reduced with circular plan.

V. Rajesh et.al., (2016) aims to provide economical section based on geometry, cross section supports and stability of rc structure. First loads are calculated based on specific location and then analysis is carried out. It insists in providing more reinforcement in areas of high deflection and shear to improve lateral load carrying capacity of building.

Details of the proposed structure

Plan and dimension of the openings are taken from clause 12 of cyclone building and the planning and designing of the structure is built according to the MOEF (Ministry of environment, forest and climate change) as stated in the environment constrains.

Type of building: Rectangular & circular building

Number of storeys: G+5

Total Gross area for rectangular building: 1296 m²

Total Gross area for circular building: 1256 m²

The building consists of

- Office rooms
- Bath rooms
- Storage room
- Waiting rooms
- Reception
- Pantry rooms
- Rest rooms
- Administrative office

Figures and Tables

Plan for rectangular building

- a) The ground floor plan of the G+5 rectangular building was prepared in AutoCAD as mentioned below in the **Fig. 1** and the total gross area is 1296 m².

Fig. 1 Ground floor plan for rectangular building

The Fig. 1 illustrates that the Dimensions of openings is taken from clause 12 of cyclone resistance building architecture prepared under GOI – UNDP, Disaster Risk management Programme.

The plan for the rest of the floors was also made using Auto CAD as shown in the Fig. 4.

Fig. 2. Plan for first to fifth of the rectangular building

The Fig 2 is the plan for the first to fifth floor which mainly consist of Hall, health clinic and bath rooms etc. It consists of two way stairs and lift so that the people may use both in case of emergency.

Plan for Circular Building

The ground floor plan of the G+5 circular building was prepared in AutoCAD as mentioned below in the figure 4.1 and the total gross area is 1256 m².

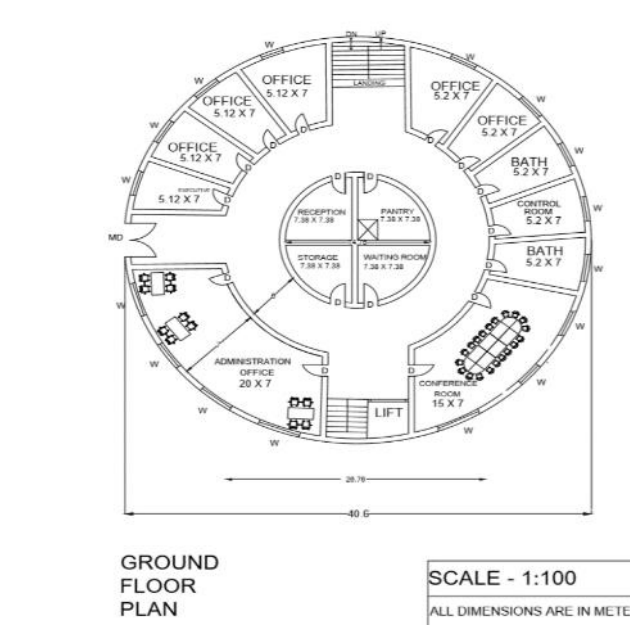

Fig. 3. Ground plan for circular building

The Fig. 3 illustrate the arrangement of the conference room, administrative room, office rooms and the Dimensions of openings is taken from clause 12 of cyclone building architecture prepared under GoI – UNDP, Disaster Risk management Programme.

The plan for the rest of the floors was also made using Auto CAD as shown in the **Fig. 4**.

Fig. 4. Plan for first to fifth floor for circular building

The **Fig. 4** is the plan for the first to fifth floor which mainly consist of Hall, health clinic, bath rooms and emergency room. It consists of two way stairs and lift so that the people may use both in case of emergency and the Dimensions of openings is taken from clause 12 of cyclone building architecture prepared under GOI – UNDP, Disaster Risk management Programme.

Analysis wind load for circular and rectangular building

The **Figs 5 and 6** shows that the wind load acting on the rectangular and circular building.

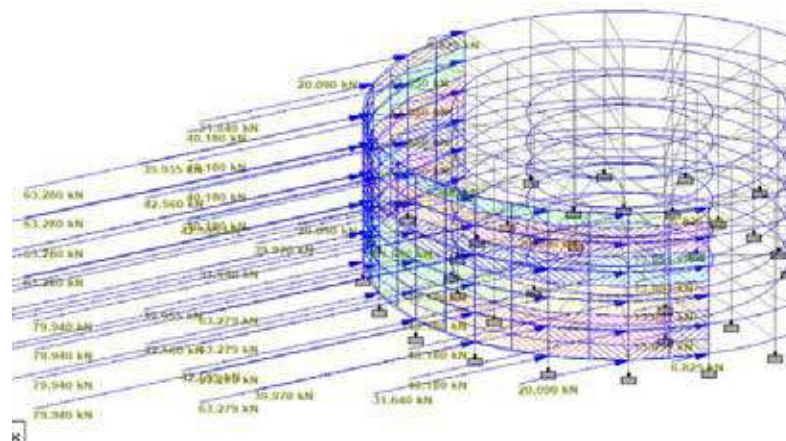

Fig. 5. Wind load for Circular Building

Fig. 6. Wind load for Rectangular Building

Analysis of rectangular structure

The 3D Rendered view was prepared by using STAAD.Pro and is shown below in **Fig 7**.

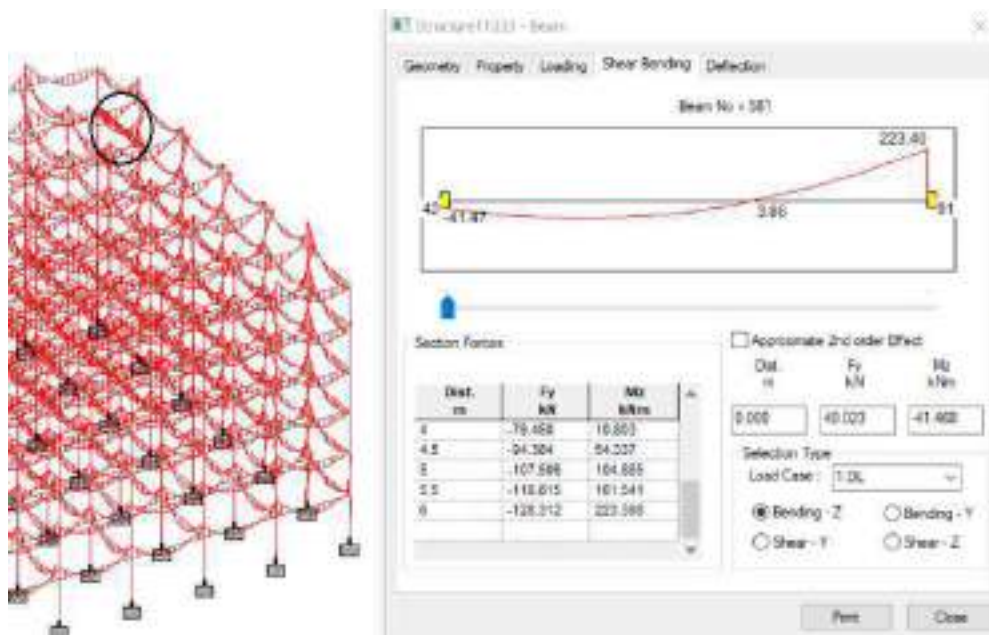

Fig. 7. 3D Rendered view for rectangular building

The Maximum bending moment =918kNm

Fig. 8. Bending moment of the Rectangular Building

Fig.8 the bending moments for rectangular building developed by using STAAD.Pro. These values can be further used for manual calculations and safety purposes.

Design Calculations

Design of Slab

1) **Given data:** Slab size = 6.0 x 7.0

Width of support = 600 mm

Depth of slab = 210 mm

Clear span = 6.0 m

Fe 415 and M20 grade

$f_{ck} = 20 \text{ N/mm}^2$, $f_y = 250 \text{ N/mm}^2$

Sides of ratio

$$L_y / L_x = 7.0 / 6.0 = 1.16 < 2$$

[Hence Two way slab]

Thickness of slab

Overall depth $D = 210 \text{ mm}$

Effective depth $d = 210 - 15 - 8 = 185 \text{ mm}$

Effective span

Effective span = Clear span + effective depth

$$= (6.0 + 0.185) = 6.185 \text{ m}$$

Load analysis

Consider 1m width of slab

Self-weight of slab = $B \times D \times \text{unit weight of concrete}$

$$DL-1 = 1 \times 0.210 \times 25 = 5.25 \text{ kN/m}^2$$

Finishes DL-2 = 1 kN/m²

Live Load = 4 kN/m²

Total service load = 10.25 kN/m²

Ultimate load (W_u) = $1.5 \times 10.25 = 15.375 \text{ kN/m}^2$

Ultimate design moment and Shear force

$$\frac{L_y}{L_x} = \frac{7.185}{6.185} = 1.16$$

From the code book IS 456:2000 refer table 9.2 and read out the moment coefficients for 1.16

$$\alpha_x = 0.065$$

$$\alpha_y = 0.056$$

$$M_{u_x} = (\alpha_x W_u L_x^2) = 0.065 \times 15.375 \times 6.185^2 = 38.23 \text{ kN-m}$$

$$M_{u_y} = (\alpha_y W_u L_x^2) = 0.056 \times 15.375 \times 6.185^2$$

$$= 30.996 \text{ kN-m}$$

$$V_u = (0.5 W_u L_x) = 0.5 \times 15.375 \times 6.185$$

$$= 46.125 \text{ kN}$$

Check for depth

$$M_{max} = 0.138 f_{ck} b d^2$$

$$D = \sqrt{\frac{30.996 \times 10^6}{0.138 \times 20 \times 1000}} = 105 < 210 \text{ mm}$$

Hence, the effective depth selected is sufficient to resist the design ultimate moment.

$$(A_{st})_{\min} = (0.0012 \times 1000 \times 210) = 252 \text{ mm}^2$$

Reinforcement (short and long span)

Along shorter span in X – direction (middle strip)

$$\text{width of middle strip} = \frac{3}{4} L_y = 5.38 \text{ m}$$

$$M_{ux} = 0.87 A_{st} F_y d \left[1 - \frac{A_{st} F_y}{b d f_{ck}} \right]$$

$$38.23 \times 10^6 = (0.87 \times 250 A_{st} \times 185)$$

$$\left[1 - \frac{250 A_{st}}{1000 \times 185 \times 20} \right]$$

$$A_{st} = 1020 \text{ mm}^2 > A_{st \min}$$

Provide 16 mm diameter bars at 200 mm centre to centre spacing in middle strip of width 5.3 m.

Along longer span in Y – direction (middle strip)

$$\text{width of middle strip} = \frac{3}{4} L_x = 4.6 \text{ m}$$

$$\text{Effective depth} = (185 - 4 - 4) = 177 \text{ mm}$$

$$M_u = 0.87 A_{st} F_y d \left[1 - \frac{A_{st} F_y}{b d f_{ck}} \right]$$

$$30.996 \times 10^6 = (0.87 \times 250 A_{st} \times 177)$$

$$\left[1 - \frac{250 A_{st}}{1000 \times 177 \times 20} \right]$$

$$A_{st} = 856 \text{ mm}^2 > A_{st \min}$$

Provide 16 mm diameter bars at 230 mm centre to centre spacing in middle strip of width 4.6m

Reinforcement in edge strips:

$$A_{st \min} = 0.12 \text{ percent of cross-sectional area} = (0.0012 \times 1000 \times 210) = 252 \text{ mm}^2$$

Provide 10 mm diameter of bars at 300mm centres.

Check for shear stress

$$\tau_v = \left[\frac{V_u}{b d} \right] = \left[\frac{46.125 \times 1000}{1000 \times 185} \right]$$

$$= 0.249 \text{ N/mm}^2$$

$$P_t = \left[\frac{100 A_{st}}{b d} \right] = \left[\frac{100 \times 1020}{1000 \times 185} \right]$$

$$= 0.508 \%$$

$$K \tau_c = (1.23 \times 0.249) = 0.306 \text{ N/mm}^2 > \tau_v$$

Hence the shear stress are within safe permissible limits

Check for cracking:

Steel provides is more than the minimum percentage of 0.12 percent

$$\left[\frac{L}{D}\right]_{\max} = \left[\frac{L}{D}\right]_{\text{Basic}} \times k_t \times k_c$$

$$= 20 \times 1.6 = 32$$

$$\left[\frac{L}{D}\right]_{\text{Provided}} = 29.5$$

$$\left[\frac{L}{D}\right]_{\max} > \left[\frac{L}{D}\right]_{\text{provided}}$$

Hence cracks will be within permissible limits as per the specifications of IS: 456 code.

Torsional Reinforcement: As per Cl D - 1.8 IS 456:2000

$$A_{st \text{ torsion}} = \frac{3}{4} \times A_{st} = \frac{3}{4} \times 1020 = 763.63 \text{ mm}^2$$

$$\text{Size of mesh} = \left(\frac{Lx}{5}\right) = 1200 \text{ mm}$$

Using 10 mm dia. Bars

$$\text{Spacing} = 1000 \frac{a_{st}}{A_{st}} = 150 \text{ mm}$$

Provide 10 mm dia. Bars @ 100 mm c/c

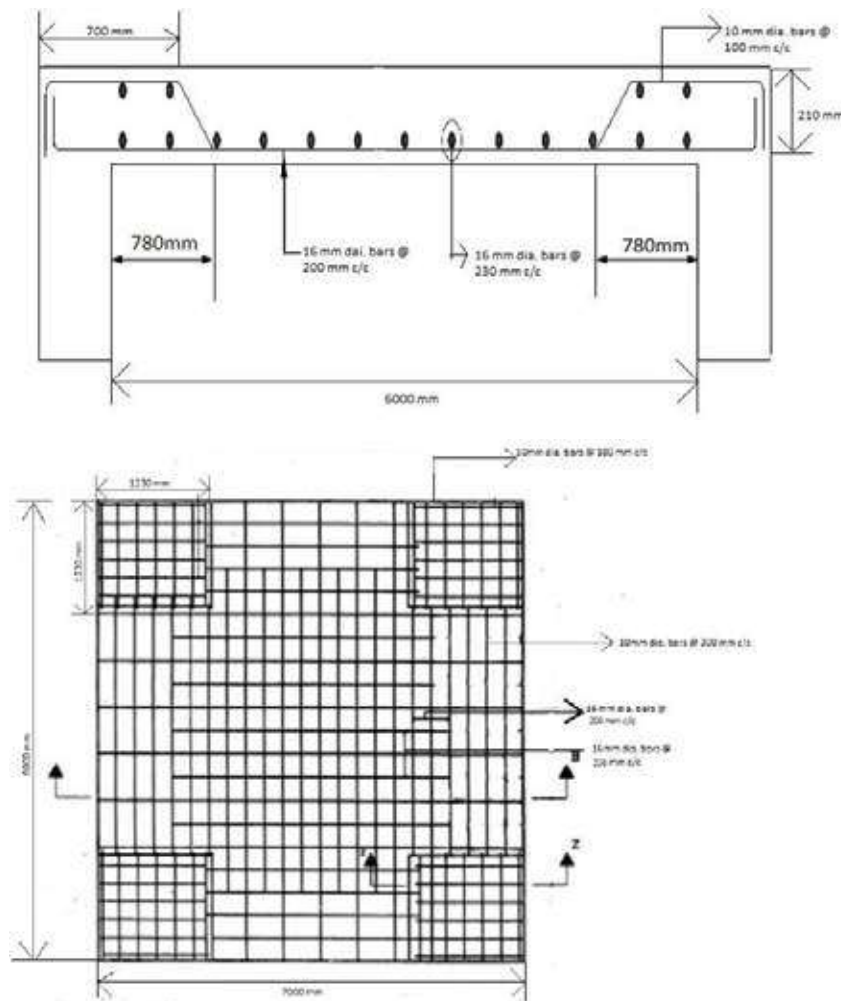

Fig. 9. Reinforcement detailing of slab

Design of Circular Beam

GIVEN DATA

Radius = 7.38

No of columns = 4

Factored load = 14.06 KN/m

$F_{ck} = 20 \text{ N/mm}^2$

$F_y = 415 \text{ N/mm}^2$

Moment and Shear force

$$\Theta = \frac{\pi}{4} = 0.785 \text{ radians}$$

$$\begin{aligned} M_u &= W r^2 \left(\frac{\theta}{\sin\theta} \cos\theta - 1 \right) \\ &= 14.06 \times (7.38)^2 \left(\frac{0.785}{\sin(45)} \cos 45 - 1 \right) \\ &= 164.64 \text{ kN/m} \end{aligned}$$

$$\begin{aligned} V_u &= W_u \times R \times \Theta \\ &= 14.06 \times 7.38 \times 0.785 \\ &= 81.4 \text{ kN} \end{aligned}$$

Max Torsion

$$\begin{aligned} T_u &= W_u R^2 \left(\frac{\theta}{\sin\theta} \sin\phi - \phi \right) \\ \phi_m &= \cos^{-1} \left(\frac{\sin\theta}{\theta} \right) \\ \phi_m &= \cos^{-1} \left(\sin \frac{45}{0.785} \right) = \cos^{-1}(0.9) = 0.45 \\ T_u &= 14.06 \times (7.38)^2 \left(\frac{0.785}{0.707} \times \sin(25.783) - 0.45 \right) \\ &= 25.23 \text{ kN/m} \end{aligned}$$

Limiting moment of resistance

$$\begin{aligned} M_{u \text{ lim}} &= 0.36 \times f_{ck} \times b \times x_m \times (d - 0.42 x_m) \\ &= 0.36 \times 20 \times 300 \times 216 (450 - 0.42(216)) \end{aligned}$$

$$M_{u \text{ lim}} = 150604120 \text{ N-mm}$$

As $M_u > M_{\text{lim}}$ section is designed as doubly reinforced beam.

$$M_{u2} = M_u - M_{u \text{ lim}} = 14395880 \text{ N-mm}$$

$$A_{st1} = \frac{M_{\text{lim}}}{0.87 \times 250 \times (450 - 90.72)} = 2111 \text{ mm}^2$$

$$A_{st2} = \frac{M_{u2}}{0.87 \times 415 \times (450 - 50)} = 150 \text{ mm}^2$$

$$A_{st} = 2261 \text{ mm}^2$$

Provide 5 bars of 25 mm diameter at bottom.

$$A_{sc} = \frac{M_{u2}}{f_{sc}(450 - 50)} = 230 \text{ mm}^2$$

Provide 2 bars of 12 mm diameter at top.

Provide 2 bars of 12 mm diameter at top.

Check for Shear:

$$\tau_v = \left[\frac{Vu}{bd} \right]$$

$$= \frac{81.4 \times 1000}{300 \times 450} = 0.60$$

$$P_t = \frac{100 Ast}{bd} = 1.81$$

$$\tau_c = 0.77 \text{ (Table 19 IS 456)}$$

$$\tau_v < \tau_c$$

Hence no shear reinforcement is to be provided, however provide 12mm Ø stirrups.

$$\text{Spacing} = 113 \times 4150.4 \times 300 = 300 \text{ mm centres} < 0.75d \text{ Adopt spacing } 300 \text{ mm}$$

Check for Torsion

$$\text{Equivalent shear } V_e = V_u + 1.6 \left[\frac{T_u}{b} \right]$$

$$V_u = W_u \times R (\phi - \phi_m)$$

$$= 14.06 \times 7.38 (0.785 - 0.45)$$

$$= 34.76 \text{ kN}$$

$$V_e = 34.76 + 1.6 \times \frac{25.23}{300}$$

$$= 134.594 \text{ Kn}$$

$$\tau_v = \frac{134.594 \times 10^3}{300 \times 450}$$

$$\tau_v = 0.996 \text{ N/mm}^2$$

$$P_t = \frac{100 Ast}{b \times d} = \frac{245400}{300 \times 450} = 1.81$$

$$\tau_c = 0.77 \text{ (Table 19 IS 456)}$$

$\tau_v > \tau_c$ hence shear reinforcement is to be provided.

Shear Reinforcement

Transverse reinforcement:

$$A_{sv} = \frac{T_u \times S_v}{bd \times (0.87) f_y} + \frac{V_u \times S_v}{2.3 d_1 (0.87) f_y}$$

Provide 12mm Ø stirrups – 2 legged

$$2 \times \frac{\pi \times 12^2}{4} = \frac{25.23 \times S_v}{300 \times 500 \times (0.87) \times 415} + \frac{34.76 \times S_v}{2.3 \times 500 \times (0.87) \times 415}$$

$$S_v = 420 \text{ mm centre to centre}$$

2. Longitudinal Reinforcement

$$\frac{A_{sv}}{b \times S_v} = \frac{0.4}{0.8 \times f_y}$$

$$\frac{75058}{0.4 \times 300} = S_v$$

$$S_v = 550 \text{ mm}$$

7) Equivalent Bending Moment

$$M_e = M_u + \frac{T_u \left(1 + \frac{d}{b}\right)}{1.7}$$

$$M_u = W_u \times R^2 \left(\frac{1.7}{\sin \theta} \times \cos \theta - 1 \right)$$

$$M_e = 164 + \frac{25.23 \left(1 + \frac{450}{300}\right)}{1.7}$$

$$M_e = 201 \text{ kN-m}$$

$$M_u = 0.87 \times f_y \times A_{st} \times (d - 0.42x_u)$$

$$A_{st} = 3342 \text{ mm}^2$$

Extra reinforcement = 3342 - 2261 = 1181 mm² Use 12 bars of 16 mm diameter

Fig. 10. Reinforcement detailing of beam

Design of Footing

Vertical load (w) = 3578 kN

Self-Weight of footing @10%=357.8 kN

Total load =3935.8 kN

Base of footing = (300×500) mm

Safe bearing capacity of soil = 250 kN/m²

Size of footing = 3935.8/250 = 15.7 m²

Let ratio of length to width be equal to 2, $y = 2x$

So area = $2x^2 = 15.74 \text{ m}^2$

$x = 2.80 \text{ m}$ and $y = 5.60 \text{ m}$

Pressure due to column load only, = $3578/5.60 \times 2.80 = 228.1 \text{ kN/m}^2$

Factored soil pressure $p_0 = 1.5 \times 228.1 = 342.28 \text{ kN/m}^2$

Calculation of depth of footing

Depth based on one-way shear

Shear force in longer direction = $p_0 \times Y (0.5(x-a)-d)$

= $342.28 \times 5.60(0.5(2.8-0.3)-d)$

= $2395.96 - 1915.12 \times d$

Shear force in shorter direction = $p_0 X (0.5(y-b)-d)$

= $342.28 \times 2.80 (0.5(5.6-0.5)-d)$

= $2443.76 - 958 \times d$

Shear force resisted by concrete = $\tau_c X d$

= $0.32 \times 10^3 \times 2.80 \times d$

= $896d$

Equating above equations we get

$2443.76 - 958 \times d = 896d$

Depth = 1.318 m

Depth based on two-way shear

For two way shear section critical section lies at $d/2$ from the column face all around:

Shear force at critical section = $p_{0(xy-(a+b) \times (b+d))}$

= $342.28(15.53 - 0.8d - d^2)$

= $5315.6 - 273.82 - 342.28 d^2$

Punching shear resisted by section = $\tau_c \times A$

= $\tau_c = 0.25\sqrt{20}$

= $0.25\sqrt{20}$

= 1.11 N/mm^2

Area of critical section = $((0.3 + d) + (0.6 + d)) \times d$

= $0.9d + 2d^2$

Shear force resisted = $1.118 \times 10^3 \times (0.9d + 2d^2)$

= $1006.2d + 2236d^2$

Equating above equations we get

$5315.6 - 273.82 - 342.28 d^2 = 1006.2d + 2236d^2$

$$2578d^2 + 1006.2d - 5589.42 = 0$$

$$d = 1.29 \text{ m}$$

Depth of Footing by Bending Moment Criterion

Critical section is at the face of column so Bending Moment at the critical section is:

$$\begin{aligned} M_{ux} &= \frac{P_u}{8} (x - a)^2 \\ &= 42.785 \times (2.8 - 0.3)^2 \\ &= 267.40 \text{ kN-m} \end{aligned}$$

$$\begin{aligned} M_{uy} &= \frac{P_u}{8} (Y - b)^2 \\ &= 42.785 \times (5.6 - 0.5)^2 \end{aligned}$$

= 1112.83 kN-m, Hence moment in larger direction is more

Moment of resistance in longer direction,

$$\begin{aligned} M_r &= 0.138 \times f_{ck} b d^2 \\ &= 0.138 \times 20 \times 2800 \times d^2 \\ &= 7728 d^2 \end{aligned}$$

Now,

$$1112.83 \times 10^6 = 7728 d^2$$

$$d = 380 \text{ mm} = 0.380 \text{ m}$$

Hence, the highest value of 'd' is adopted as: 1.318 m

Overall depth, D = 1318 + 50 + 8 = 1350 mm

$$d = 1292 \text{ mm}$$

Area of reinforcement

$$M_u = 0.87 F_y A_{st} d \left[1 - \frac{A_{st} F_y}{b d f_{ck}} \right]$$

a) For longer direction

$$1112.83 \times 10^6 = 0.87 \times 250 \times A_{st} \times 1292 \left[1 - \frac{A_{st} \times 250}{2800 \times 1292 \times 20} \right]$$

$$A_{st} = 4505 \text{ mm}^2$$

$$\text{Spacing} = \frac{201}{4 \times 0.87} \times 2800 = 140 \text{ mm}$$

Use 16 mm ϕ bar @ 120 mm spacing

For shorter direction

$$267.40 \times 10^6 = 281010 A_{st} - 1.727 A_{st}^2$$

$$A_{st} = 953 \text{ mm}^2$$

$$A_{st \text{ min}} = (0.0012 \times 1292 \times 2800) = 4341 \text{ mm}^2$$

$$A_{st} < A_{st \text{ min}}$$

As per codal provisions, $\frac{\text{reinforcement in central band}}{\text{total reinforcement in short direction}} =$

$$\frac{2}{\beta + 1}$$

Where $\beta = 2$

Reinforcement in central band = $4341 \times \frac{2}{3} = 2894 \text{ mm}^2$

Reinforcement shall be distributed in central 2.8 width

Spacing of 16mm ϕ bars = $\frac{201}{2894} \times 2800 = 194 \text{ mm}$

Use 16 mm ϕ bar @194 mm spacing in central band

Balanced area of steel to be distributed in outer bands = 3388 mm^2

Spacing = $2013388 \times 2800 = 160 \text{ mm}$

Use 16 mm ϕ bar @160 mm for the outer bands

Fig. 11. Reinforcement detailing of footing

Design of Column

Given data

$P_u = 5660 \text{ kN}$

$L = 3.5 \text{ m}$

$f_{ck} = 20 \text{ N/mm}^2$

$$f_y = 415 \text{ N/mm}^2$$

$$D_y = 300 \text{ mm}$$

$$D_x = 500 \text{ mm}$$

$$M_u = 135 \text{ Kn-m}$$

|Slenderness ratio

$$\left(\frac{L}{D_y}\right) = 11.6 < 12$$

Hence, it is a short column.

Minimum eccentricity

$$E_{x \text{ min}} = \left(\frac{L}{500}\right) + \left(\frac{D_x}{30}\right) = 24 > 20 \text{ mm}$$

$$E_{y \text{ min}} = \left(\frac{L}{500}\right) + \left(\frac{D_y}{30}\right) = 17 < 20 \text{ mm}$$

As $\frac{e_{\text{min}}}{d} < 0.05$ Hence, the column is designed as

Axially Loaded Short Column

Non dimensional parameters

$$\left(\frac{P_u}{f_{ck} b d}\right) = \frac{5660 \times 1000}{20 \times 300 \times 500} = 0.864$$

$$\left(\frac{M_u}{f_{ck} b d^2}\right) = \frac{135 \times 10^6}{20 \times 300 \times 500^2} = 0.09$$

Longitudinal reinforcement

Chart 32 SP: 16

Cover = 50 mm

$$d / D = 0.10$$

$$\frac{P}{f_{ck}} = 0.04$$

$$P = 0.04 \times 20 = 0.8$$

$$A_{sc} = \frac{P b D}{100} = \frac{0.8 \times 300 \times 500}{100} = 1200 \text{ mm}^2$$

$$A_{st} = 490.625 \text{ mm}^2$$

$$\text{Number of bars} = \frac{1200}{\frac{\pi}{4} \times d^2} = \frac{1200}{490} = 6 \text{ bars}$$

Provide 6 bars of 25 mm diameters with 4 bars distributed on longer face.

Fig. 12. Reinforcement detailing of column

CONCLUSION

- The process described has been assessed under the environmental impacts of all elements of the cyclone resistant evacuation shelter.
- The plan of the building is prepared using AutoCAD while considering all the requirements as per Disaster Risk Management Programme.
- The cyclone resistant evacuation shelter was analysed for various loads such as dead load, live load and wind load as per the guidelines of the Indian Standards. The analysis was carried out using STAAD.Pro.
- The cyclone resistant evacuation shelter has been designed for all the loads applicable and the loads have been calculated as per Indian Standards.
- Whereas the maximum bending moment in circular cyclone resistant evacuation shelter was found to be 809 KNm while as that of rectangular cyclone resistant evacuation shelter was found to be 918 kNm. Hence due to less bending moment in circular cyclone resistant evacuation shelter it is more effective in cyclone prone areas.
- The structure which is found to be safe and designed according to Indian standards is also found to be a substitute to the cyclone resistant evacuation shelter and has been found to be much more efficient and economical. Hence can be implemented in cyclone prone areas and serve in a much efficient way.

Study on Comparative Advantages of E350 vs. E250 Grade Steel in Industrial Structures

Amresh Kumar*, Saptadip Sarkar, Anurag Sinha

Structural Division, Engineers India Limited, New Delhi

*✉ amresh.kumar@eil.co.in

ABSTRACT

Use of structural steel of grade E350 conforming to IS 2062 has seen an increase in India specially, in industrial structures. The reasons for this increased use is essentially high mechanical strength, good tensile strength, easy formability, good ductility, high shear strength etc. However the limitations on easy availability and higher cost of E350 than E250 Grade steel it raises the doubts about impact on overall cost to the project. Therefore, it is imperative to perform a comparative analysis of these two most used steel grades in Indian structural engineering on basis of design strength and steel quantity requirements, to enable the designers to select the appropriate grade, fitting the functional requirements and economics of the project. This study summarizes the comparative benefits of using E350 instead of E250 grade steel by presenting a theoretical comparison as well as a case study of two industrial technological structures in hydrocarbon industry.

Keywords: E350 grade steel; E250 Grade steel; Yield strength; IS 2062; Industrial structures; Cost Benefits.

INTRODUCTION

E350 grade structural steel (conforming to IS 2062) is gaining popularity in industrial structures in India due to its higher mechanical strength and tensile strength, easy formability, good ductility, higher shear strength etc. However, the availability of E350 grade is not easy for full spectrum of hot rolled sections especially when required in small quantities and in remote areas. This adds transportation and delay costs in already higher prices of E350 grade steel as compared to E250 steel. Further, designers are usually asked to replace the structural member of one grade to another in order to expedite the procurement, which is mostly (and sometimes wrongly) done increasing or decreasing the design properties in ratio of yield strength, ignoring the effect of other important factors such as section size, effective length and slenderness etc. This study attempts to study the comparative benefits of using E350 grade steel in place of E250 grade steel from the strength and cost advantages point of view.

OBJECTIVE

The study is designed to examine the following w.r.t. the use of E350 grade steel instead of E250 grade-

- I. Extent of gain in design capacities and the relation of the same with section size and slenderness
- II. Change in overall quantity of structural steel in technological structures
- III. Extent of variation in cost of structure
- IV. Other qualitative and operational/functional benefits.

METHODOLOGY

To establish the aforementioned objectives, this study is designed in following parts-

Comparison based on theoretical design capacities

This part contains calculation of ultimate bending and axial capacities of hot rolled I- and channel sections as per relevant sections of IS 800-2007 (Limit State Design) by varying the slenderness and grade of steel to establish the relation between relative gain when steel grade is changed from E250 to E350.

This is done in following steps

- i. Comparison of allowable bending moments of Indian Isections for varying effective lengths (1.25 m, 2.5 m & 3.75 m) for lateral torsional buckling,
- ii. Comparison of allowable bending moments of Indian Channel sections for varying effective lengths (1.25 m, 2.5 m & 3.75 m)for lateral torsional buckling,
- iii. Comparison of allowable axial force of Indian Isections for varying effective lengths (2.0 m, 4.0 m & 6.0 m)for slenderness,

Comparison based on actual design

To access how far the difference in capacities achieved in first part, translate into reduction in required steel quantity for actual structures, a comparison of structural steel quantity required in technological structures in a refinery is presented considering the grade of steel as E250 and E350. For getting the idea of dependence of variation in quantity on section sizes used, one lightly loaded non-equipment supporting structure and one heavily loaded equipment supporting structure (**Fig. 1**) is selected and design is performed in STAAD Pro Select series v8i using IS 800-2007 (LSM) as design code. For ease of identification following nomenclature is adopted-

TS_L_E250: Lightly loaded Technological Structure designed for optimum sections using E250 grade steel TS_L_E350: Lightly loaded Technological Structure designed for optimum sections using E350 grade steel

TS_H_E250: Heavily loaded Technological Structure designed for optimum sections using grade E250 steel

TS_H_E350: Heavily loaded Technological Structure designed for optimum sections using Grade E350 steel

Table 1. Gives the details of the structures used for this comparative analysis

Based on analysis and design of above structures, a comparison of structural steel quantity required for TS_L_E250 and TS_H_E250 vis-à-vis TS_L_E350 and TS_H_E350, respectively, is presented to estimate the reduction in steel requirement in actual structures.

1(a)-Structure considered for TS_L_E250 and TS_L_E350 1(b)-Structure considered for TS_H_E250 and TS_H_E350

Analysis of Qualitative Benefits

Benefits of using E350 grade from operational and durability point of view are highlighted.

RESULTS AND DISCUSSION

A direct comparison of yield strength of E350 grade and E250 grade indicates that a 40% gain is expected ($350/250=1.4$) and as a misconception usually it is followed that when replacing E350 steel member with E250 steel member, design properties shall be increased by 40% and vice-versa. This idea completely ignores the effect of section size and effective length of the member. This fact needs to be examined with respect to the findings based on design capacities of individual members as discussed below. Comparison of design moment capacities for commonly used hot rolled I-section beams is presented in **Fig. 2** and for hot rolled channel beams in **Fig. 3**. Similar comparison of design axial compression capacities for I-section columns is shown in **Fig. 4**. A. Effect on Bending capacity of I-beams:

Fig. 2(a), (b) & (c) show that for all three L_{eff} (i.e. 1.25m, 2.5m and 3.75m), design moment capacities increase with change of yield strength from E250 to E350, which is obvious. But interestingly, the increase in moment capacities is dependent on section size and as the section size increases, percentage gain in capacity also increases. When the gain in moment capacity is averaged for all sections, average percentages are 35.63% for $L_{eff} = 1.25m$, 30.00% for $L_{eff} = 2.5m$ and 22.82 for $L_{eff} = 3.75m$. It indicates that if the member unrestrained lengths are large, the relative gains due to use of higher grade steel are lost to some extent. **Table 2** presents the summary of findings for I-sections in form of percentage change in design capacities. From the table, an important fact to be noted is that gain in moment capacity is almost constant (in the range of ~30-38%) for all wide flange sections (with exception of WPB600x300x128.79) for all three values of L_{eff} and is very close to the increase in yield strength (i.e. 40%). The increase in moment capacity of ISMB sections is also in the same range but only for $L_{eff} = 1.25m$ and as L_{eff} increases moment capacity decreases sharply.

Table 2. Summary of increase in capacity of I-sections of e350 vs. e250 grade steel

EFFECTIVE LENGTH (M)	INCREASE IN BENDING MOMENT CAPACITY			INCREASE IN AXIAL COMPRESSION CAPACITY		
	1.25	2.5	3.75	2	4	6
SECTION SIZE	% DIFF	% DIFF	% DIFF	% DIFF	% DIFF	% DIFF
MB300	36.19	22.29	9.90	24.02	3.67	1.66

MB450	36.54	23.75	10.55	26.36	4.23	1.83
MB500	37.34	28.17	13.80	31.22	6.50	2.43
MB 600	35.63	30.56	19.41	32.42	10.68	3.39
WPB 600@128.79	23.30	21.61	17.83	37.67	29.16	12.42
WPB 600@177.77	36.99	35.17	32.62	35.64	29.90	15.67
WPB 700@149.89	38.80	36.75	32.03	37.56	28.21	11.35
WPB 700@204.48	36.78	35.04	32.18	35.56	29.24	14.42
WPB 700@240.51	36.83	35.09	32.46	35.57	29.34	14.60
WPB 800@262.33	36.63	34.95	31.98	35.49	28.68	13.48
WPB 900@291.45	36.46	34.84	31.59	35.42	28.10	12.61
AVERAGE	35.63	30.00	22.82	32.55	19.28	8.79

Fig. 2(a) Design bending moment capacity of I-section beams of $L_{eff} = 1.25m$

Fig. 2(b) Design bending moment capacity of I-section beams of $L_{eff} = 2.5m$

Fig. 2(c) Design bending moment capacity of I-section beams of $L_{eff} = 3.75m$

Fig. 2. Design bending moment capacity of I-section beams

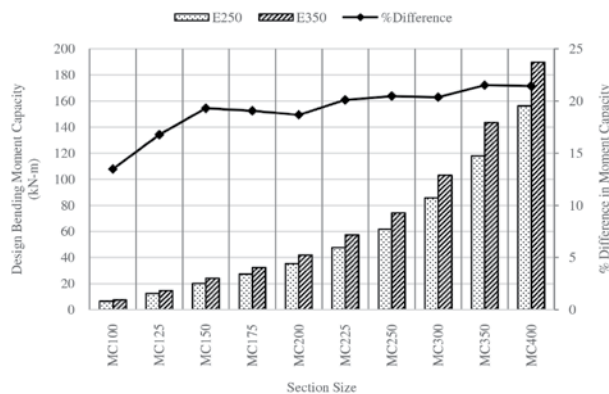

Effect on Bending Capacities of Channel beams

Fig. 3(a), (b) & (c) show that for all three L_{eff} , design moment capacities increase with change of yield strength from E250 to E350, and like I-beams, the increase in moment capacities is dependent on section size. As the section size increases, percentage gain in capacity also increases. When the gain in moment capacity is averaged for all sections, average percentages are 34.45% for $L_{eff} = 1.25m$, 19.12% for $L_{eff} = 2.5m$ and 9.07% for $L_{eff} = 3.75m$. Thus for channel sections also, the benefits in terms of increased moment capacity are more prominent when unrestrained lengths are small. Gain in smaller channel sections is not much as compared to larger sections and as effective length, and consequently slenderness, increases the gain in capacity decreases.

3(a) Design bending moment capacity of channel beams of $L_{eff} = 1.25m$

3(b) Design bending moment capacity of Channel beams of $L_{eff} = 2.5m$

3(c) Design bending moment capacity of Channel beams of $L_{eff} = 3.75m$

Fig. 3. Design bending moment capacity of Channel beams

Effect on Axial compression capacities of I-columns

Fig. 4(a), (b) & (c) show that for all three effective lengths (i.e. 2.0m, 4.0m and 6.0m), like design moment capacity, design axial compression capacity also increases with change of yield strength from E250 to E350 and increase in axial capacity is dependent on section size and effective length of column section. Percentage gain in axial capacity, averaged for all sections, are 32.55% for $L_{eff} = 2.0m$, 19.28% for $L_{eff} = 4.0m$ and 8.79% for $L_{eff} = 6.0m$. It indicates that if the member unrestrained lengths are large, the relative gains due to use of higher grade steel are lost to some extent. Table 2 indicates that as L_{eff} increases, the average gain is reduced because due to increase in slenderness, reduction in allowable stress as per IS800-2007 becomes prominent irrespective of the steel grade.

Further Table 2 and Fig. 4 indicate, that gain in axial capacity is almost constant for one value of L_{eff} for all wide flange sections (e.g. 35.42-37.67% for $L_{eff} = 2.0m$, 28.10-29.90% for $L_{eff} = 4.0m$ and 11.35-15.67% for $L_{eff} = 6.0m$) however the gain sharply reduces with increase in L_{eff} . In case of $L_{eff} = 4.0m$ average increase in axial capacity is 28.95% for wide flange sections and only 5.74% for ISMB sections. These values are much lower than increase in yield strength (i.e. 40%).

4(a) Design axial compression capacity of I-section columns of $L_{eff} = 2.0m$

4(b) Design axial compression capacity of I-section columns of $L_{eff} = 4.0m$

4(c) Design axial compression capacity of I-section columns of $L_{eff} = 6.0m$

Fig. 4. Design axial compression capacity of I-section columns

Effect on Structural Steel Requirement and overall cost in Technological structures

Structural steel quantities for the technological structures selected for study are presented in Table-III. Structural steel required for TS_L_E350 is 8.80% less than that of TS_L_E250, while for TS_H_E350 it is only 5.46% less than that of TS_H_E250. It shows that actual gain in terms of reduced structural quantity by using E350 grade steel instead of E250 are 8.80% and 5.46% for light and heavy structure, respectively.

Thus actual gain in overall structures is much less than as expected based on individual member capacities. The reason for this is that in actual structure each member can't be provided the optimum section arrived by design because it will result in large variety of sections. Instead, for ease of procurement, some standard sections only are used and members having similar behavior are grouped and are provided largest size required by any members of that group. Further, for some members (e.g. tie members) slenderness becomes the governing criteria and even though the smaller section is sufficient from stress point of view, larger section is provided to achieve required slenderness. Hence, even if E350 grade steel is used, section size for these members can't be reduced as minimum radius of gyration (r_y) is required to be maintained.

Section sizes required in heavier structure are large than those required for lighter structure. Hence the percentage reduction in structural quantity in heavier structure is expected to be more than that for lighter structure. However, values in Table 3 are not in line with this. The reason for this may be that due to standardization of section sizes and grouping of members, some members are always underutilized so even if yield strength is reduced, the section size is not required to be increased due to already available reserved capacity. Further, the reduction in overall steel quantity for a structure will depend on the percentage of heavier and lighter sections in the structure. Therefore further study with large number of structures and varying percentage of members used as beams and columns may be required to establish this point.

While designing the structures, only allowable stresses and slenderness ratio have been considered for determining the required section size. If the stricter deflection requirements in industrial structures and shear capacity of connections are also considered, it may be possible that section sizes can't be reduced even if smaller section of E350 grade is sufficient by bending moment criteria. Thus, the comparative gain is further reduced. But as the deflection requirement and shear capacity of connection requirements are usually the governing criteria for beams supporting very heavy equipments only, the effect may not have much impact on steel requirement for overall structural.

Effect on overall Cost of Steel Structure

Cost of structural steel works includes mainly three components: material cost, fabrication cost and erection cost. Material cost of E350 grade steel is approximately 5-7% higher than E250 grade steel. As per code requirement, welding material shall be of same or better grade than the base metal. Hence, for grade E350 steel, use of E70 rods is compulsory whereas for E250 steel, E60 rods can be used. As former is found to be at least 25% costlier and welding cost contributes to approximately 10% of the

total fabrication cost, fabrication cost for E350 steel can be said to 2.5% more than E250. Erection cost can be assumed not to be directly affected by grade of material used.

Table 3. Summary of change in overall quantity and cost of structures

STRUCTURE NAME	STEEL QUANTITY (KN)	% DIFFERENCE IN QUANTITY	STEEL COST (INR/KG)	FABRICATION COST (INR/KG)	ERECTION COST (INR/KG)	TOTAL COST (INR/KG)	% DIFFERENCE IN COST PER KG	TOTAL COST (IN M INR)	% DIFFERENCE IN OVERALL COST
TS_L_E250	489.04	-8.80%	45	35	20	100.00	4.03%	48.90	-5.13%
TS_L_E350	445.99		48.15	35.875	20	104.03		46.39	
TS_H_E250	2362.78	-5.46%	45	35	20	100.00	4.03%	236.28	-1.65%
TS_H_E350	2233.88		48.15	35.875	20	104.03		232.38	

Based on these, a cost comparison is presented in **Table 3** for the technological structures. As exact price of steel works vary depending on various factors, a normalized value of 100 INR/Kg is assumed for E250 grade with 45%, 35% and 20% weightage for material, fabrication and erection costs respectively.

Table 3 shows even though the material cost and fabrication cost for E350 grade are higher, it results in reduction in overall cost of the structure. However this reduction is only 5.13% for lightly loaded structure and 1.65% for heavy structure which is not very significant considering the increase in yield strength and design capacities of individual members. This is an important point to be kept in mind while finalizing the tender quantities and cost estimation for structural steel works.

Qualitative benefits of E350 grade steel

Other than increased yield and ultimate strength E350 grade steel possesses some better qualitative properties, owing to its higher carbon equivalent value, such as resistance to acids in elevated temperature, resistance to pitting and crevice corrosion, and resistance to oxidation, chloride stress and cracking corrosion. E350 grade steel works at high temperature and shows hardness and toughness at the cryogenic to high temperature. Due to these reasons, E350 grade steel is well preferred for using in nuclear plants, refineries, petro-chemical plants and fertilizer plants.

CONCLUSION

Summarily, present study highlights following points regarding the use of E350 grade steel-

- The use of 1.25 m as unrestrained length of beams is an ideal condition where in maximum capacity of the beams can be utilized. It gives a benefit of up to 36% in moment capacity if E350 grade steel is used instead of E250 grade.
- For columns, effective length of 4.0 m, which is the most commonly used length as per industry practices; use of E350 grade steel gives a benefit of 10.67% in axial compression capacity against E250 grade steel.
- The benefits of using E350 grade steel is more prominent in wide flange sections and members with smaller unrestrained lengths.
- The benefits in increased design capacity by using E350 grade instead of E250 grade are not directly proportional to ratio of yield strengths and are largely dependent on slenderness ratio. Structural engineers should always keep this in mind while suggesting section replacements.
- The impact of using E350 grade instead of E250 grade on overall structural steel quantity of structures is very limited due to section standardization and grouping. Hence, it is suggested that at the time of tendering, structural steel quantities shall not be reduced on account of using E350 grade.
- Even though E350 grade steel being costlier, the extra cost is mostly balanced by reduced quantity. However, the impact of reduced quantity is found to be approximately ~5% or less, hence this cost reduction may be ignored while finalizing the costing of the entire project especially in LSTK contracts.

Thus, this study establishes that benefits of E350 grade vs. E250 grade steel are very limited considering the overall project. However, this study doesn't discourage the use of it but only warns against overestimating the benefits merely looking at the increased yield strength.

On one hand, use of E350 can save a lot of fabrication time as the quantity of built-up sections can be reduced. Also, hidden advantages in material handling and transportation are also there. But on the other hand; E350 grade steel is not very easily available especially if smaller quantity distributed over large variety of sections is required. The problem of availability is more severe for wide flange sections because the availability is subjected to minimum quantity of ordering and number of producers is also limited. Further, it is suggested that for projects where in very heavy loads and very tall structures are anticipated, use of E350 is preferred whereas in minor structures and temporary structures use of E250 may be preferred.

ABSTRACT

This paper highlights the concept of floating solar PV plant and deals with the floating solar photo voltaic design, development using numerical analysis. Floating components are made up of HDPE which show superior performance and are cost effective. CFD analysis is executed on the structure for the study of flow and assessment of wind pressure on the developed model using Indian environmental conditions. The CFD results have been compared and validated with the analytical calculations obtained through IS 875 codes part 3 for wind pressure. Also, Structural FE analysis is carried out to ensure structural stability for the given environmental conditions.

Keywords: Floating solar PV plant; Green energy; High Density Polyethylene (HDPE), FEA analysis; CFD Simulation; IS 875- part 3.

INTRODUCTION

In recent times, solar energy usage is growing rapidly as it is considered as one of the most promising energy alternatives due to its sustainability and eco-friendly nature. All over the world solar energy is available to a large extent. Frequent use of solar energy is through Photovoltaic (PV) system. The main difficulty for the same is the availability of land. Ground-Mount type installation has the pressure of land requirement, which is an expensive resource. Hence to overcome the cost of solar projects and make it economically feasible, installation of Solar Power Plant on water bodies can become a very logical alternative.

This concept of installing solar power plant on water bodies will not only boost the economic viability of the solar projects but will also increase the efficiency of the plant as the operating temperature is less underneath the panels. [1] Additionally, it also reduces water loss due to evaporation and inhibits algae growth due to shading of water. [2] We identify the possible design solutions for the floating structure addressing the key challenges and established a solar farm model in CAD.

The most normally used floating platforms are template type platforms made of Steel, Fiber- reinforced plastic FRP, High density polyethylene (HDPE) and used in marine, aerospace etc. industries. [4] The design and analysis of these floating structures must be made in accordance with layout of water bodies and in assistance with anchoring and mooring system. The design and analysis of floating platforms must be done taking into consideration many factors, including the following important constraints:

- Environmental conditions and undesirable disruptions like wave load, fatigue load.
- Water bodies characteristics for suitable choice of material.
- Code requirements (e.g. Indian Standard Codes "IS" codes)
- Intensity level of consequences of failure.

The entire design, installation, and operation must be approved by the client. Important features of the components are as follows.

- Environmentally friendly, easy installing and dismantling, Safety, Maintenance free and cost effective.
- Design Versatility, No Sharp Corner.
- High Load Capacity, UV Resistant.

The floating platforms are made up of High-Density Polyethylene (HDPE) which can withstand ultraviolet rays and corrosion.

Pontoons made up of heavy molecular weight high density polyethylene and other additive's as raw material are strong, tough and durable, resistant to UV rays, salt water and oil, chemical corrosions.

Concept of floating solar PV plant

A Floating Solar technology results from a combination of PV plant technology and floating technology. A Floating body consists of connecting Structure and Floats. Floaters are the components that float on water bodies with buoyancy enough to mount PV modules. An array of such floaters forms a solar farm and is designed as per the requirement. Structures are the supporting system which connects the Floats and the PV modules. According to research, having this effective cover of Floating Structure and PV Modules has caused a reduction in evaporation of water from the reservoir. [2] Floaters consist of pontoons, connectors, solar panels, and cables.

Pontoon is a floating component of the floatation system with the required buoyancy to float with a heavy load to maintain stability. The Platform is designed as per the required number of panels. Solar PV crystalline panels are widely used for floating solar PV systems. As any metal corrodes with time, the polymer made frame must be used.

Fig 1. Floating solar plant working Schematic [16]

Cables and Connectors – The power through solar modules can be stored in solar batteries or fed to the grid. To transfer power to the distribution line, robust and waterproof cables are used to provide a long Service. India today is fastest growing market for renewable energy in the world. India visions a renewable energy target of 175 Gigawatt by year 2020 in which energy from solar sources is 100 GW. The country has been building rapid advances in this area. As such, it is obvious that floating solar would become a technology for consideration by policymakers in the country.

LITERATURE REVIEW

Alok Sahu et al [2] highlights the concept of the floating PV system and compares it with the land-based Installation. In India, Source of water bodies are easily available and thus this technique serves as a complementary advantage. In addition to all positive aspects, proper design consideration such as wind, water stability, temperature limit, snow load, cyclone, and typhoon, etc. should be considered. Also, proper azimuth tilt and angle as per geographical location should be considered. It is found to produce 1.2 times the current production of PV on lands. Luyao Liu et al [11] studied the power generation effectiveness of the floating solar PV plant and analyzed the capacity of a floating solar PV system with respect to terrestrial solar PV system. It was estimated that floating PV system is almost increased by 2% in comparison with the land-based PV system.

Young-Geun Lee et al [4] designed and constructed a floating PV generation system with actual construction. Composition of Unit structure and process of large scale floating system was suggested. As per material cost, a brief analysis was performed of the structural system fabricated with different materials. It was found that the structural system with FRP is the most cost-effective due to the lightweight. Overall, the above example was a positive experience for the construction of large scale floating system in the near future. Sun-Hee Kim et al [3] showed that in comparison to conventional constructing materials, FRP and HDPE has good mechanical properties and also corrosion– resistance.

Girma T. Bitsuamlak et al [8] Studied different cases for various wind angle of attack on standalone ground mounted solar panels. The solar panel experienced the highest overall wind loads for 0°degree wind angle of attack i.e. upwind case. Veysel Emre Uslu et al [7] concluded that panel length has a major impact on solar panels. Also, spacing factor is an important factor for designing a solar farm. First row panels are subjected to higher wind loads when panel length increases. Wael Charfi

[10] showed that Solar PV system performance is enhanced due to its open design which facilitates natural ventilation. A 3D CFD model describing the performance of the system is developed and compared with the experimental data. Paturi Lakshmi Prasanna Kumar et al [5] concluded the angle of attack of wind on surface plays an important role to study the mean pressure distribution. It was observed that pressure was maximum at 0° and 180° . Puneeth kumaar HP [6] studied variations of lift and drag force with the change in the angle of attack. It was found that at 30° , the lift force is higher than the drag force.

GEOMETRIC MODEL

Design Consideration

The concept of installing Solar PV modules on water bodies is complex and requires proper planning, construction and hence key design factors must be taken into account carefully. The factors taken into account were the Layout of the pond, Floating structure geometry, Orientation of PV panel [2]. The floating solar power plant is constructed by connecting pontoons using connection pin/bolts to minimize the bending moment induced by unstable movement of water surface [3]. As per the geographical location, tilt angle was kept at 10 degrees.

The model designed was optimized enough to minimize weight by eliminating unnecessary material and at the same time should sustain environmental conditions. The location of installation was India and therefore wind speed was kept at a maximum speed of 60m/s considering coastal region effect. (IS875).

Design of Unit Structures and Formation of Solarfarm

A unit structure consisting of solar module, Main Float and Walkway Float (Floating System which is composed of HDPE) and connecting members are as shown in below figure. Additional members are aluminum purlin which connects the PV module and the main floats using bolts to maintain stable contact. Connection pin devices bring into line the lug to lug connection of floats and customs a solar panel farm. All the components were modelled in CAD platform. The HDPE Float members are optimized enough to provide the buoyancy for heavy load and at the same time withstand forces on it. HDPE being cost-effective is also lightweight, provides high strength.

The length of all the members is kept within an assortment for ease in handling and maintenance. The Floating PV generation system consists of several Floats as per the desired power output. Each panel has a capacity of 330W, in which panels arranged in rows and columns with the dimension of 1962×992 mm per panel are installed. The total plant capacity depends on the space and panel arrangement. The solar farm formed by array of solar panels is as per the layout of water bodies and supported by the anchoring system which retains.

Fig 2. Unit Structure displaying Main and Walkway Float

the position of the structure when subjected to any wave disruption. The anchoring and mooring system is firm enough to maintain the steadiness of assembly for the subjected wind speed and wave disturbance.

CFD ANALYSIS

A 3D CFD models interpreting the solar PV system is developed. A grid dependency test was carried out and we selected a mesh size of 710587 cells. The mesh type was cut cell method. The generated mesh is shown in **Fig 3**.

Fig 3. Meshed model for CFD analysis

As the system is subjected to load due to the wind, the forces acting on the panel is computed by CFD analysis. In the mentioned analysis, CFD methodology is used to figure out the force and pressure developed by wind on the Solar panels to wind incident angle of 0°, 90° and 180° for wind flow. Solar panels at 10° angle of orientation are studied at 60 m/s wind speed. The CFD model is developed with a fixed wind speed under the steady state condition. The information of input data is given in **Tables 1 and 2.**

2. LEEWARD-180°
3. SIDEWIND-90°

The modeling process consists of first taking the real world fluid characteristics and imitating this in the simulated environment. From here, a mesh is created to divide the fluid volume into discrete sections. In this CFD Domain, anything that doesn't have a flow condition applied to the volume is excluded i.e. cavities without flow are excluded. Boundary conditions are then entered into the model to term parameters such flow inlet/outlet, type of fluid to be taken, details of any solid edges, domain dimensions etc. The domain for CFD simulation is shaped so as to develop a high flow on stationary surfaces. The free exposure of Structure with panels to wind is studied. Domain Size is 20×5×8 for all conditions. The CFD simulation computed the forces on various panel surfaces is shaped so as to develop a high flow on stationary surfaces and wind pressure was evaluated from the forces. As a result, maximum pressure is considered for steady state analysis.

As computed, the maximum lift generated force due to wind flow for windward condition is 1120 N and for leeward condition is 940.5 N and hence accordingly, analysis for the same load condition needs to carry out for respective load conditions. It is clear enough from CFD analysis that high pressure is observed for upwind condition due to high variation in flow and hence a certainty factor should be taken into account to calculate design wind Pressure.

STRUCTURAL ANALYSIS FOR UPWIND

To examine the magnitude of induced stresses arising from various design loads, a design-by analysis approach using finite element methods has been necessary because of the absence of suitable design-by-rule methods for the design features requiring assessment. In order to get wind pressures, CFD on 5Cx4R Floating solar farm was done, which is then used in following FEA, so as to check the strength and stability of component. The site location is India with a basic wind speed of 60m/s.

Material data

Table 3. Material data

Material	HDPE
Density	960 kg/m ³
Youngs Modulus	1450 MPa
Proof Strength	29 MPa
Poissons Ratio	0.4
Allowable stress	14.5 MPa

Note:

- 1) Material Data is taken from [12].
- 2) Allowable Stress is S_y / FOS ; where $FOS = 2$ for all components.

Boundary Condition and Loads

The analysis aims to provide the verification of structural stability considering dead load, wind and wave loads for the Floating solar farm by means of the structural FE analysis. The system which constitutes a photovoltaic array(s) is designed to withstand the extreme fair wind (positive pressure) and adverse wind (negative pressure) on design tilt angle of solar photovoltaic array(s).

- a) For individual strength checks, inner faces (hole) of lugs are constrained in all directions.
- b) Wind force on the panel due to wind loading is applied on the Panel face as normal force. Wind pressure for Load due to fair wind direction on design tilt angle of panel, Load due to adverse wind direction on design tilt angle of panel and Load on side face of components is considered. All the values are obtained as per CFD see Section III.
- c) Self-weights are directly taken by FEA software from given densities.
- d) Since Geometry and loading is symmetrical, it is convenient to solve the problem by considering Symmetry in FEA. Thus, in fig all the models are shown in halves, because of Symmetric boundary condition.

Fig 4. Boundary conditions and load for upwind

Design Wind Pressure

Maximum Force is computed through CFD analysis and is used for evaluation of Wind Pressure for the worst load condition as shown below

As, Pressure = Force/Area

Panel Exposed Area to wind = 1962 × 992 = 1946304 mm²

Thus,

Upwind pressure through CFD analysis = 1120 / (1.946304) = 575.44 Pa

To account for uncertainties

Design upwind pressure = 1.5 × 575.44 = 863.174 Pa. Here factor 1.5 is used to consider a Gust safety factor.

Stress Plot

As per the above analysis, the induced stress in all the component are within the permissible limit and hence the designed components for the given material with required additives is safe for the given load condition.

Fig 5. Equivalent stress plot for upwind

FATIGUE ANALYSIS

As floats of solar mounting floating system are subjected to alternate stresses due to waves and other varying external disturbance, fatigue analysis is important to evaluate actual life of the system. To avoid fatigue failure, fundamental requirements during design and manufacturing phase is a must. Hence the following work addresses the same and analyzes the components for fatigue loading.

Fig 6. Boundary conditions and load for 5° load condition

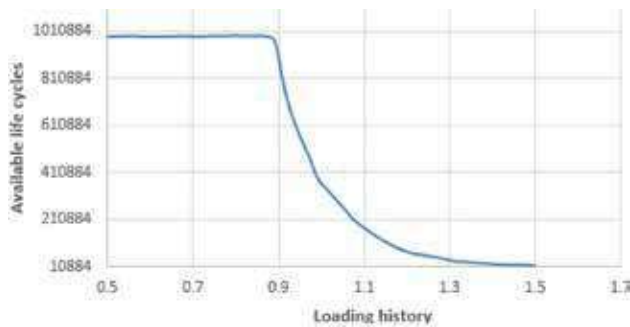

Fig 7. Fatigue sensitivity plot for 5°

Note: This plot shows % loading on X axis and Life cycle on Y axis. On X –axis, 0.5 corresponds to 50% of load applied.

The floats are fixed at connection point and allowed to rotate about z axis for different load combination (**Fig 6**). In the same way, other rotations were assigned the boundary conditions. The available load combination is chosen as per standard target set for floats i.e. safety check design life of 360000 cycles for 15°, 10° and 5°. Safety factor plot and Fatigue sensitivity plot for the described load condition is studied and analyzed accordingly. It can be clearly interpreted from the graph that increasing number of life cycles for respective load condition is more safer for 5° and then for 10° and then ultimately for 15°. Hence, the developed model is more suitable for calm and less wavy.

RESULT SUMMARY

Table 4. Stress assessment for upwind condition

Component	Induced Stress(M Pa)	Allowable Stress (M Pa)
Main Float	13.69	14.5
Walkway Float	14.35	14.5
Dead load for unit system + 100kg Live Load	9.84	14.5

Table 5. Wind pressure comparison

Wind Pressure (Pa)	Method	
	CFD Simulation	Analytical analysis (IS 875)
Upwind	863.174	838.44
Downwind	724.83	503.064

As understood from above table 4, it can be concluded that stress in upwind condition which is worst case as per CFD simulation is within permissible limit and is safe for desired service for the HDPE material. Also, from **Table 6**, can be concluded that the CFD results are approximately similar to the analytical approach using IS codes 875 part 3. Fatigue analysis concludes that the developed model is more safer for 5° Load condition for design life of 360000 cycles, whereas for 10° and 15° load condition the components fails at minute regions for the available life cycle.

CONCLUSION

This paper highlights the concept of Floating Solar Technology, develops a design and CFD model and discusses the important results and outcomes.

Maximum wind speed, the heavy load should be considered in the analysis. A proper study of factors like the layout of a water body, Orientation and Geometry of structure, tilt angle, etc. must be carried out for better results. Although HDPE shows superior performance and is reliable, FRP can also ascertain to be a worth replacement.

CFD simulation indicates that high wind pressure is subjected near panel region during the upwind load condition and hence the probability of failure at this condition is high and hence accordingly maximum lift force is considered for Structural analysis. Upwind load condition should be taken as the worst case and design and analysis should be done for the same case.

Static structural analysis was carried in FEA software for the upwind condition and the work demonstrates that stresses arising in the specified areas are within allowable limits and that the floating solar farm is therefore satisfactory for the intended service. Fatigue check for number of cycles to failure as per standard guidelines for float was studied and the system for the given material is safe and more reliable for less intense wavy water bodies. Wind pressure from CFD analysis was close to analytical analysis as per the IS code (Analytical analysis). Compared to land based installation, almost 42% installation cost is saved in floating PV plant. Also, the payback period is less in floating solar PV system..We hope that this article will assist researchers to address issues in near future in the area of Floating solar installation and development.

ABSTRACT

The basic concept of the Performance Based Seismic Design (PBSD) is to provide engineers with the capability to design buildings that have a predictable and reliable performance in earthquakes. The main time consuming step in the evaluation of performance of the building due to earthquake ground motion is the procedures to be followed in the Nonlinear Dynamic Analysis. So the identification of ground motion parameters having good correlation with the structural response and development of Structural Response Functions are significant in the performance assessment of multi-storied buildings. This paper describes the basic concepts of the PBSD and the findings of various researchers on this area. The major steps in the development of Structural Response Functions include collection of strong motion data, evaluation of ground motion parameters, Nonlinear Dynamic Analysis on various buildings, calculation of structural response parameters and multivariate regression analysis of ground motion parameters on the structural response parameters. The complexity of the analysis can be simplified by developing the response functions.

Keywords: Performance based seismic design; Ground motion; Structural response; Nonlinear dynamic analysis, Multivariate regression analysis.

INTRODUCTION

The Performance Based Seismic Design (PBSD) process explicitly evaluates how a building is likely to perform, given the potential hazard it is likely to experience, considering uncertainties inherent in the quantification of potential hazard and the assessment of the actual building response. The basic concept of the PBSD is to provide engineers with the capability to design buildings that have a predictable and reliable performance in earthquakes. It is a design methodology done on the probable performance of the building under input ground motions. Due to the recent advances in seismic hazard assessment, PBSD methodologies, experimental facilities, and computer applications, Performance Based Seismic Design has become increasingly more attractive to developers and engineers of buildings in seismic regions. The seismic design of buildings typically was developed using performance-based capacity design procedures in which the engineer proportioned the building for intended nonlinear response and then used nonlinear structural analysis to verify that the structure's performance would be acceptable when subjected to various levels of ground shaking. So the strength based design is slowly giving way to the performance based design. The guidelines for PBSD are given in FEMA 356, FEMA 445, ATC 40, ATC 58 etc.

Severe damages of multi-storied buildings due to the earthquakes lead the engineers and seismologists to investigate the ground motion characteristics and structural seismic effects. The structural responses are correlated with simple ground motion parameters viz., peak ground or spectral response acceleration at fundamental period of the structure for predicting the seismic response of structures. These measures of ground motion intensity are chosen because they correspond to existing seismic hazard models. Other ground motion characteristics or parameters need to be identified that correlate better with seismic performance, particularly for the cases when the structural systems becomes nonlinear and its dynamic properties change with ground motion intensity. The identification of the ground motion characteristics or parameters will drive the development of corresponding seismic hazard data and models that can be combined with structural response or damage data and models serving to a good prediction in the performance assessment process. This study focuses mainly in correlating the ground motion parameters and the structural response of the multi-storeyed reinforced concrete buildings.

GROUND MOTION PARAMETERS

Ground motion parameters are essential for describing the important characteristics of strong ground motion and to develop

Ground motion prediction equations. S. L. Kramer [12] explains the main characteristics of earthquake ground motion as follows:

- 1) Amplitude
- 2) Frequency Content
- 3) Duration

Amplitude Parameters

- 1) *Peak Ground Acceleration (PGA)*: the largest absolute value of horizontal acceleration obtained from the accelerogram of that component.
- 2) *Peak Ground Velocity (PGV)*: the greatest speed of shaking recorded at particular point during an earthquake.
- 3) *Peak Ground Displacement (PGD)*: the greatest distance moved by the ground at particular point during an earthquake.
- 4) *Effective Acceleration*: the acceleration which is most closely related to structural response and to damage potential of an earthquake.
- 5) *Sustained Maximum Acceleration (Velocity)*: The lower peaks of the accelerogram is used to characterize strong motion by defining the Sustained Maximum Acceleration (Velocity) for three or five cycles as the third or fifth highest absolute value of acceleration(velocity) in the time history.
- 6) *Effective Design Acceleration*: the peak acceleration that remains after filtering out accelerations above 8 Hz.

Frequency Content Parameters

1) *Ground Motion Spectra*: Any periodic function can be expressed using Fourier analysis as the sum of a series of harmonic terms of different frequency, amplitude and phase. Using the Fourier series, a complete description of the ground motion can be provided since the motion can be completely recovered by the inverse Fourier spectrum as:

$$x(t) = c_0 + \sum_{n=1}^{\infty} (c_n \sin(\omega_n t + \phi_n))$$

Where c_n and Φ_n are the amplitude and phase angle, respectively of the n th harmonic of the Fourier series.

2) *Fourier Spectra*: Fourier transform brings a motion in the time domain to the frequency domain. A plot of Fourier amplitude versus frequency is known as Fourier amplitude spectrum.

3) *Power Spectra*: The frequency content of a ground motion can be described by a power spectrum or power spectral density function. The total intensity of a ground motion of duration T_d is given in the time domain by the area under the time history of squared acceleration as:

$$I_0 = \int_0^{T_d} [a(t)]^2 dt$$

4) *Response Spectra*: describes the maximum response of a Single Degree of Freedom (SDOF) system to a particular input motion as a function of the natural frequency or natural period and damping ratio of the SDOF system.

5) *Predominant Period*: the period of vibration corresponding to the maximum value of the Fourier Amplitude Spectrum.

6) *Bandwidth*: the range of frequency over which some level of Fourier amplitude is exceeded.

7) *Shape Factor*: indicates the dispersion of the power spectral density function about the central frequency.

8) v_{max}/a_{max} : Because peak velocities and peak accelerations are usually associated with motions of different frequency, the ratio v_{max}/a_{max} should be related to the frequency content of the motion

Duration Parameters

1) *Bracketed duration*: the interval between the points in time where the acceleration amplitude first and last exceeds a prescribed level.

2) *Significant duration (Td)*: the time trace required to build up from 5% to 95% of the integral for the total duration of the recorded motion.

Other Parameters

1) *rms Acceleration*: a single parameter that includes the effects of the amplitude and frequency content of a strong motion record.

$$a_{rms} = \sqrt{\frac{1}{T_d} \int_0^{T_d} [a(t)]^2 dt}$$

2) *Arias intensity*: a parameter closely related to the rms acceleration.

$$I_a = \frac{\pi}{2g} \sqrt{\frac{1}{T_d} \int_0^{T_d} [a(t)]^2 dt}$$

3) *Cumulative absolute velocity*: the area under the absolute accelerogram.

$$CAV = \int_0^{T_d} |a(t)| dt$$

4) *Response spectrum intensity*: The area under the pseudo-velocity response spectrum between periods of 0.1 and 2.5 seconds.

5) *Effective peak acceleration*: the average spectral acceleration over the period range 0.1 to 0.5 seconds divided by 2.5.

6) *Effective Peak Velocity*: the average spectral velocity at a period of 1 second divided by 2.5.

7) *Damage potential*: a parameter incorporates the effects of strong motion duration on the response of medium rise buildings and is expressed as:

$$I = PGV T_{d0.25}$$

8) *Cosenza-Manfredi metric*: a dimensionless duration metric expressed as:

$$CMM = \frac{\int_0^{t_{max}} a^2 dt}{PGA \times PGV}$$

Where

t_{max} = Length of the accelerogram

STRUCTURAL RESPONSEPARAMETERS

The output from Nonlinear Time History analysis includes peak values of displacement, nonlinear deformation demands and component forces. From these demand sets following key response parameters are developed to represent the structural and non-structural damage of the buildings due to earthquake shaking [11].

A. *Interstory Drift Ratio*: ratio of interstory displacement to story height. It depends on several factors including structure’s mass, stiffness, strength, damping and the ground motion record.

B. *Park-Ang Index*: a damage index combining both ductility and cumulative hysteretic energy demand [10].

$$D_{PA} = \frac{d_m}{d_u} + \frac{\hat{a}}{V_y d_u} \int dE_h$$

Where

d_u = ultimate deformation capacity under monotonic static loading

d_m = maximum deformation demand under dynamic loading

dE_h = incremental hysteretic energy demand

V_y = yield strength

β = a non-negative non-dimensional parameter

C. *Floor Acceleration and Velocity* : represented for the estimation of damage of non-structural elements. Floor velocity is calculated by numerical differentiation which consists of dividing the difference in the floor at adjacent time steps by the size of the step. Floor acceleration is obtained by taking a second numerical differential which consists of dividing the difference in floor velocities at adjacent time steps by the size of the time step [11].

D. *Residual Drift Ratio*: highly sensitive to component modelling assumptions related to post-yield hardening/softening slope and unloading response and is evaluated by the following equations:

$$\Delta_r = 0, \text{ for } \Delta < \Delta_y$$

$$\Delta_r = 0.3(\Delta - \Delta_y), \text{ for } \Delta_y < \Delta < 4\Delta_y$$

$$\Delta_r = (\Delta - 3\Delta_y), \text{ for } \Delta > 4\Delta_y$$

Where

Δ = maximum storey drift ratio

Δ_y = median storey drift ratio calculated at yield

LITERATURE REVIEW

The US Federal Emergency Management Agency (FEMA) published the guidelines for the Performance Based Seismic Design (PBSD) from time to time. According to FEMA-445 [7] PBSD is an iterative process and the major steps in the procedure are as follows:

- 1) Select performance objectives
- 2) Develop preliminary building design
- 3) Characterization of ground shaking hazard
- 4) Select a desired yield mechanism and target drift for the design earthquake hazard
- 5) Perform analysis of the structure
- 6) Conversion of base Shear – displacement curve to ADRS Spectra
- 7) Revise design

The FEMA-356 [8] identifies the following performance levels and adopts roof-level lateral drift at the corresponding load levels as a measure of the associated behaviour states of the building

1) *Operational (O)* : very light damage, no permanent drift, structure substantially retains original strength and stiffness, minor cracking of facades, partitions, and ceilings as well as structural elements, all systems important to normal operation are functional.

2) *Immediate Occupancy (IO)* : no permanent drift, structure substantially retains original strength and stiffness, minor cracking of facades, partitions, and ceilings as well as structural elements, elevators can be restarted, fire protection operable.

3) *Life Safety Level (LS)*: moderate, some residual strength and stiffness left in all stories, gravity-load bearing elements function, no out-of-plane failure of walls or tipping of parapets, some permanent drift, damage to partitions, building may be beyond economical repair.

4) *Collapse Prevention Level (CP)*: severe, little residual stiffness and strength but load-bearing columns and walls function, large permanent drifts, some exits blocked, infills and unbraced parapets failed or at incipient failure, building is near collapse.

A K Chopra [13] and ATC-40 [9] described the general procedures adopted for analysis of multi-storied buildings in the performance based seismic design process. They are linear static, linear dynamic, nonlinear static, and nonlinear dynamic

analyses. Linear static analysis can only be used for regular structure with limited height. The main disadvantage of linear static analysis is that it will not consider the inelastic behaviour of the structure. The static nonlinear analysis or pushover analysis allows the inelastic behaviour of the structure and provides reasonable estimation of the global deformation capacity of the structure and so is more efficient than linear static analysis. The dynamic analysis is classified as Response Spectrum and Time History Analyses. The Response Spectrum Analysis is an elastic dynamic analysis of a structure utilizing the peak dynamic response of all modes having a significant contribution to total structural response. The Time History Analysis is the analysis of the dynamic response of a structure at each increment of time when the base is subjected to a specific ground motion time history. It is performed with pairs of appropriate horizontal ground motion time history components that are selected and scaled from minimum three recorded events. The Nonlinear Time History Analysis (NTHA) is performed when high degree of accuracy is desired for obtaining the structural response of the multi-storied buildings during earthquake ground motion. In the case of inelastic systems the lateral resisting forces are dependent on the prior history of motion and a numerical integration method is used to solve the differential equations of motion to obtain the time history of the response. By selecting the Nonlinear Time History Analysis nonlinear inelastic response and the time-history of the seismic response of the structure are obtained. So this method is more accurate than linear static, response spectrum, and nonlinear static or pushover analyses.

As a result of the development work by the ATC-58 project of the US Federal Emergency Management Agency (FEMA) three series of volumes referred to as FEMA P-58 [11] was published in 2012. These volumes describe the methodology for seismic performance assessment of individual building that properly accounts for uncertainty in the ability to accurately predict the structural response. The inputs of this methodology include the development of basic building information, response quantities, fragilities and consequence data. The FEMA P-58 procedures are probabilistic, uncertainties are explicitly considered and the seismic performance of buildings followed by earthquake ground motion is expressed as the probable consequences in terms of human losses, direct economic losses and indirect losses. The methodology is applicable for all types of buildings if basic data on structural and non-structural damageability are available.

A Massumi and F Gholami [1] conducted a study of correlation between the ground motion and structural response by selecting 85 far-field ground motion records from 17 earthquake events with magnitudes in the range 5.9-7.6 from the PEER strong motion database. Non-linear dynamic analyses of four reinforced concrete frames were performed using IDARC-20 software. Principal Component Regression Analysis was performed by taking time-dependent and frequency-dependent ground motion parameters as dependent variables and inter-storey drift, roof drift and Park-Ang Index as dependent variables. It was observed that frequency-dependent parameters were better correlated than time-dependent parameters to predict the structural damage during an earthquake.

G Molas, M Rahnama and P Seneviratna [2] performed the Time History Analyses by selecting 480 records from the 7 earthquakes on 3 and 9 storied steel frame structures using DRAIN-2DX software. The maximum inter-storey drift was obtained as output and is converted into the Mean Damage Ratio (MDR) which was taken as dependent parameter. The Peak Ground Acceleration (PGA), Peak Ground Velocity (PGV), and Acceleration Response Spectra amplitudes (S_a) for the periods 0.3 and 1 seconds were taken as the ground motion parameters or independent variables. A Neural Network Model is used to find the relation between the ground motion and structural response parameters. It was observed that better correlation is attained when the full set of input ground motion parameters are used.

A Elenas [3] developed a procedure to evaluate the post seismic damage of multi-storied buildings. 400 records of past earthquakes were selected and evaluated 20 ground motion parameters. Non-linear dynamic analysis was performed on various models of multi-storied buildings and Overall Structural Damage Indices (OSDIs) such as Park and Ang, Maximum Interstorey Drift Ratio (MISDR) and Maximum Softening Index of Dipasquale and Cakmak were selected as damage indices. Multilinear regression analysis and Discriminant analysis were performed to find the correlation between the ground motion parameters and the damage indices. Also a structural response function was developed combining the effect of all the ground motion parameters and the structural response. The accuracy of the equation is tested by creating another set of artificial accelerograms.

M Ellassaly [4] conducted Non-linear dynamic analyses on a two dimensional model of a 12 storey RCC building using the computer program IDARC2D V.6.1 subjected to 21 earthquake records. The study was focused on the effect of the Peak Ground Acceleration (PGA) and frequency contents on the structural response due to the ground motion. The frequency content was represented by the A/V ratio where A is the Peak Ground Acceleration (PGA) and V is the Peak Ground Velocity (PGV). Park and Ang Index and Interstorey Drift Ratio were selected as damage indices. The records were classified into LFC, MFC and HFC for low, medium and high frequency contents. It was concluded that when the A/V ratio increases both Park and Ang Index and Interstorey Drift Ratio of the buildings decreases.

K Kostinakis, M Papadopoulos, A Athanatpoulou and K Morfidis[5] conducted a study on the correlation between structure-specific ground motion intensity measures and the damage indices. The intensity measures were evaluated by the Pushover Analysis on RCC buildings by selecting 20 pairs of earthquake ground motions from the PEER strong motion database with magnitudes between 5.5 and 7.8. Then Nonlinear Time history Analyses was performed on four 5-storey buildings for each of the ground motions using the computer programme Ruaumoko. The Maximum Interstory Drift Ratio (MIDR) and Overall Structural Damage Index (OSDI) were taken as the structural response parameters. The Pearson correlation coefficient is taken as the indicator to evaluate the correlation between the intensity measures and the seismic performance parameters. And it was observed that the spectral acceleration at the fundamental mode period is having good correlation with the structural damage of the buildings compared to other intensity measures.

S Chakroborty and R Roy[6] studied the role of important ground motion characteristics on the demand of a plan asymmetric system by using a number of records with widely varying characteristics but adjusted to a common spectral shape. Because ground motion components are generated from the same earthquake source and seismic waves that travel through the same medium, strong dependence between the temporal and spectral characteristics of the two components was expected. Orientation of the ground motion axis with respect to the structural axis had been shown to play an important role in regulating response. A change in the orientation of ground motion components was associated with a corresponding change in ρ_{xy} which had been considered an important parameter for record selection in bidirectional analysis. It was also concluded that significant duration (T_d), frequency content, mean period (T_m) and the correlation coefficient (ρ_{xy}) between two horizontal earthquake components of a record might be chosen as characteristic ground motion parameters. Also the relevance of the energetic length scale (L_e) on the inelastic responses of irregular systems was explored.

CONCLUSION

The significance of the Performance Based Design and the studies on the correlation between ground motion parameters and the structural response parameters are reviewed. By developing Structural Response Functions the complexity of Nonlinear Dynamic Analysis can be avoided in the evaluation of seismic performance of the buildings during ground motion. The effect of various ground motion parameters and its effects on the response of buildings, considering many geometrical and structural parameters are to be investigated in future for simplifying the procedures in the Performance Based Seismic Design process.

ABSTRACT

Hong Kong discards between 4-6 million disposable face masks every day. The global figure is estimated in the billions. The bulk of the discarded face masks are sent to the landfill along with Municipality Solid Waste (MSW). Based on the estimation that each face mask weighs two to three grams, the face masks disposed of at landfills every day weigh at least 10 to 15 tonnes. But a significant number end up polluting the environment. In this paper, we describe a method to sanitize the used facemasks and also recycle them into useful concrete products. It involves the collection of used facemasks, sanitizing the same using ozone treatment, shredding them, and mixing them in a suitably designed cement-based composite to make products like bricks, tiles, slabs, etc. The paper describes the results of preliminary experiments that establish the feasibility of the approach as concrete mixes with a range of densities and compressive strengths are produced.

Keywords: PPE; Face mask; Covid19; Papercrete; Recycling; Concrete.

BACKGROUND & INTRODUCTION

The building construction sector is one of the main components of the global economy directly accounting for 6% of global GDP [1]. Concrete is arguably the most widely used construction material in the world. At about 20 billion metric tons or around 2.5 metric tons per person on an annual basis in 2013 [2] it is being consumed at an ever-increasing rate. For example, between 2011 and 2013, China consumed 6.6 gigatons of concrete¹ – more than what the US used in the entire 20th century. The consumption of materials in general and construction material in particular has driven the growth of the economy. An indicator of this growth is the consumption of cement². Since 2010, China's consumption has increased from 2.05 billion tons per year to 2.35 billion tons with a high of 2.7 billion tons³ in 2014. In the same period, the world consumption of cement has increased from 3.64 billion tons to 4.65 billion tons. Construction is also one of the largest employment generators in most countries –being highly labor-intensive. In a world where developed countries like the USA, Canada, Europe, Japan, and Australia, etc have more or less reached a point of saturation, the future growth in construction is bound to come from fast-developing economies of countries like China, India, south-east Asia, South America, and Africa. In the developed world, the investment in repair and replacement of existing infrastructure will outpace new construction. With the growing threat of climate crisis, the construction sector is going to face the challenge of reducing its carbon footprint of about 25-40% emission out of which 7-8% is contributed by the manufacturing of cement alone. There are efforts to make the entire construction sector achieve net-zero carbon by 2050 by way of the use of green materials in construction and renewable energy in the operation of buildings. [3]

Overall municipal solid waste (MSW) generation will increase to 3.40 billion metric tons by 2050 from around 2.01 billion tonnes currently as per a World Bank report⁴. In 2016, the world produced 242 million tonnes of plastic waste which was

¹ <https://www.forbes.com/sites/niallmccarthy/2014/12/05/china-used-moreconcrete-in-3-years-than-the-u-s-used-in-the-entire-20th-century-infograp hic/#3493a5ed4131>

² <https://www.globalcement.com/magazine/articles/858-defining-the-trendcement-consumption-vs-gdp>

³ <https://www.statista.com/statistics/1042516/chinese-cement-consumption/>

⁴ <https://www.wastedive.com/news/world-bank-global-waste-generation-2050/533031/>

12 percent of all municipal solid waste. It is estimated that only 13.5% of today's waste is recycled and 5.5% is composted. Plastic waste is choking our oceans, yet our consumption of plastics is only increasing [4]. The Covid19 pandemic has added significantly to this crisis by a sudden increase in the consumption of Personal Protective Equipment (PPE). An estimated 1.6 billion tonnes of carbon dioxide-equivalent (CO₂-equivalent) greenhouse gas emissions were generated from solid waste in 2016, which is about 5 percent of global emissions. Without improvements, solid waste-related emissions are anticipated to increase to 2.6 billion tonnes of CO₂-equivalent by 2050. Hong Kong discards between 4-6 million disposable face masks every day. The bulk of the discarded face masks are sent to the landfill along with the general waste. Based on the estimation that four to six million face masks are used in Hong Kong daily and each face mask weighs two to three grams, the face masks disposed of at landfills every day will weigh some 10 to 15 tonnes. But a significant number end up polluting the environment including the drains, streams, beaches, and end up in the sea⁵. Panda et al. have provided a comprehensive global scenario as far as plastic waste recycling is concerned.

BRIEF REVIEW OF PRIOR RESEARCH

Fuller, B., et al. [6] have conducted a study to determine the mechanical and physical properties of Papercrete using laboratory tests for the commonly used sample mixes and compared them with anecdotal evidence. The stress-strain curve obtained suggests that papercrete is ductile and resists permanent deformations. The study conclusively states that with the proper mix design, papercrete can be safe for 2-story residential home constructions, but indicates the scope for better testing to gather more information in order to generate more conclusive evidence for it to be used for heavy-duty applications as well.

Almeshala et al. [7] have investigated the effects of using PET as a partial substitute for sand in concrete and studied their physical and mechanical properties. They crushed PET bottles to 4-0.075 mm and used in the concrete mix in different proportions to attain the desired percentage of substitution. It has been observed that the density, tensile strength, compressive strength, and workability of concrete decreases with an increase in PET in the mix. Additionally, the flexural strength is also shown to be reduced and can be explained by the low strength of plastic aggregates and low bond strength between the cement mix and the plastic aggregates due to the hydrophobic nature of plastic. It has been hence concluded that this form of substitution can be used for mechanically less intense structures and lightweight applications.

Alqahtani et al [8] have produced recycled plastic aggregate (RPA) using waste plastic and red sand filler and conducted a comparative study with respect to lightweight aggregate (LWA). It is noted that the use of plastic reduced the compressive strength of the concrete due to lower bond strength with the cement mortar and the RPA. While the permeability of LWA decreased with an increase of the Water to Cement Ratio, it remained unaffected for the RPA concretes. The concrete ion permeability of RPA concrete was observed to be much lower than the corresponding LWA concrete since plastic aggregates blocked the transfer of chloride ions. Thus this kind of concrete is recommended to be used in applications that demand low strength and inertness to chemical attacks.

Okeyinka et al. [9] have reviewed the use of solid wastes in building construction materials. The use of plastic in form of aggregates in the concrete has shown improved compressive and flexural strength but are poorly bonded to the concrete and thus require surface roughening treatment. The use of paper has been found to increase the weight to strength ratio, insulation properties, and toughness characteristics of concrete materials. However, the tensile and compressive strength is found to be reduced based on experimental tests.

Sharma and Bansal [10] have reviewed the use of different forms of waste plastic in concrete. They have also emphasized the various additives that can help in assuaging the drawbacks of plastic addition to the mix. It has been observed that the workability of the concrete reduces adding waste plastic, but the performance can be improved using a chemical treatment such as alkaline bleach treatment. They have also reported the increase in tensile strength of the concrete on plastic addition, which is attributed to the bridging action of fibers in the concrete. The flexural strength has also been observed to improve since the plastic acts as a crack arrestor. The review suggests that more research has to be done on the process of mixing, the shape, percentage ratio, and surface properties of the plastic fiber in order to ensure adherence to the mix. Durability is considered to be a major concern and hence the use of plastic is recommended to be used in relatively light-duty applications.

Shermale and Varma [11] have done a study on the compressive strength and mass density by producing papercrete with different ingredients such as fly ash, sand, and glass fiber. It has been observed that the compressive strength of the concrete is

⁵ <https://uk.reuters.com/article/uk-health-coronavirus-hongkong-environment/discarded-coronavirus-masks-clutter-hong-kong-beaches-trails-idUKKBN20Z0PI>

directly proportional to the amount of cement in the mix and inversely dependent on the amount of waste paper pulp added to the mixture. The density of the concrete reduces with the increase in the amount of paper in the mix. Thus the study suggests using papercrete for lightweight components and construction materials that are not subjected to heavy loads.

Dalhat and Wahhab [12] have evaluated the thermal and mechanical properties of recycled polystyrene (rPS) and polypropylene (rPP) concrete. Based on the testing conducted the rPP showed higher compressive strength than rPS and AC (Asphalt Concrete), almost equivalent to PCC (Portland Cement Concrete). The rPS shows high bending resistance than PCC, AC, and rPP. The rPP showed very high flexural strength whereas the rPS showed higher flexural strength than rPP and rPS. Both rPP and rPS show better moisture resistance and thermal sensitivity than AS.

Małek et al. [13] have studied the effect of the addition of recycled polypropylene on the mechanical properties of concrete. The comparison is made between three different mixing ratios (0.5%, 1%, and 1.5% wt. of cement) and two different forms of recycled PP fibers (White polypropylene fiber (PPW) and green polypropylene fiber (PPG)). A significant increase in compressive strength, flexural strength, and split tensile strength was observed on adding each type of fiber with PPG giving better results for the two.

SIGNIFICANCE OF THE RESEARCH

It is possible to sanitize the used facemasks⁶ alongside mixed waste plastics to recycle them into useful concrete products. It involves the collection of used facemasks, sanitizing the same using ozone treatment, shredding them, and mixing them in suitably designed cement-based composite mixes to make products like bricks, tiles, slabs, etc. Such an approach can help ease the burden of safe and sustainable disposal of waste plastic including PPEs.

EXPERIMENTAL PROGRAM

Materials

A preliminary experimental program was carried out to test whether shredded used sanitised face masks can be effectively incorporated in papercrete as a strategy for its recycling. Disposable face masks were collected and sanitised using ozone treatment (**Fig. 1**). They were shredded manually and using a paper shredding machine. The shredded facemasks are shown in **Fig. 2b**. The paper pulp was obtained by soaking shredded paper from the concrete laboratory office and mixing them after 3 days using a mortar mixer. The moisture content of the pulp was measured to be 94% in undrained condition and 82% after draining excess water in the pulp. A photograph of the paper pulp is shown in **Fig 2a**. The Ordinary Portland cement, local fly ash, and river sand along with tap water were used in all mixes. The mix proportions are shown in **Table 1**. The objective was to test a range of mixes with properties ranging from low strength lightweight concrete for non-structural applications to normal density and medium strength concrete for load-bearing applications.

Table 1. Mix proportions (by weight)

Sl. No.	Components	Mix I	Mix II	Mix III
1	Cement	1.0	1.0	1.0
2	Fly Ash	1.0	1.0	1.0
3	Paper (%)	50	15	0.0
4	Sand	0.0	2.0	2.0
5	Shredded face mask (%)	0.0	2.0	10
6	Water	8.4	1.4	0.8

Sample Preparation and Testing

Small quantities of material adequate to cast several 40 mm cubes were mixed by a hand mixer. All the dry ingredients were mixed first followed by mixing of water and superplasticizer as required to make a flowable mortar before adding the shredded face masks. All samples were demoulded after 2-4 days of drying as required and air-cured until testing at 28 days. A photograph of the samples is shown in **Fig. 3**.

⁶ A Hong Kong company - Zero Impact will assist in sanitising facemask using Ozone treatment - <https://zeroimpact.com.hk/>

Fig. 1. Ozone treatment machine from Bio3Gen distributed by ZeroImpact Limited (www.zeroimpact.com.hk)

Fig. 2. (a) Shredded sanitised face masks and (b) paper pulp used in the experiments

RESULTS AND DISCUSSION

The density of the three mixes was monitored as evaporation of excess water took place. **Table 2** shows the change of weight with the time of the three mixes. It also shows the average compressive strength at 28 days. The density of the papercrete (Mix I) is 0.35 g/cc while the mix with both paper and shredded face mask (Mix II) is 1.56 g/cc and the third mix with face mask only is 1.8 g/cc.

Table 2. Density (G/CC) and 28 day comp strength (MPa)

Sl. No.	Age	Mix I	Mix II	Mix III
Density (g/cc)				
1	1	0.43	1.86	2.08
2	3	0.36	1.67	1.89
3	7	0.35	1.56	1.80
Compressive Strength (MPa)*				
4	28	1.14	9.46	19.45

*Average of three test results.

Fig. 4 shows the cut section of a sample each from Mix II and III. They show the microstructure with paper and face mask and with face mask alone respectively.

Fig. 4. (a) Section of a Mix II sample with paper and face mask, and (b) Section of a Mix III sample with only face mask.

Future Work

The work presented in the paper represents a very preliminary experimental exploration of concrete mixes incorporating waste paper pulp and shredded disposable face masks. Based on these preliminary results it is demonstrated that recycling PPE waste plastic such as disposable used face masks in concrete to make a variety of useful products of different densities and strengths is feasible. A comprehensive experimental program will help optimise the mix proportions and characterise the material properties suitable for different structural and non-structural applications. Other approaches to the recycling of mixed waste plastics such as converting liquid fuel through catalytic thermolysis [5], manufacture of lightweight aggregates, using melted plastic as a binder to produce bricks, blocks, paving/roofing tiles, etc can also be explored.

SUMMARY AND CONCLUSIONS

The following conclusions can be drawn based on the information presented in this paper.

1. Disposal of waste plastics is a global challenge that has become even more critical with the pandemic generating a multitude of disposable PPEs such as face masks that need an urgent solution.
2. A preliminary experimental study shows that using shredded facemasks in concrete is a feasible approach to recycling.
3. A range of properties such as density (0.35 g/cc to 1.8 g/cc) and compressive strengths (1.14 - 19.45 MPa) are achievable.
4. Further research should be carried out to explore other approaches to recycling such as conversion to fuel, lightweight aggregate, or plastic products to manage the global menace of burgeoning waste plastics.

A Technical Paper on “RCC Blanket Wall”

H M Viswanatha Sastry

Director (Technical), Department of Civil, Bhamys Constructions Pvt. Limited, Lakshmipuram, Mysore, Karnataka

✉ sastry.hmv@bhamys.com

ABSTRACT

In the hilly and mountainous terrain many types of structural methods are used to withstand high earth pressure and also prevent soil erosion and hold the earth surface intact. The generally used techniques include building retaining walls, soil nailing, reinforced earth retaining wall (RERW) etc. These types of construction methods not only consume high quantity of steel and concrete but also increase labour and time of construction. This technical paper on “Blanket wall” for the ‘safe Protection’ of the cut & exposed/Natural surfaces of the hilly terrains will provide an alternative innovative method of construction which will reduce cost of construction, save time and re-sources without compromising on the quality, safety and intent of construction. This particular article exemplifies one of NMDC mining projects at Bailadila, Chhattisgarh.

In the course of this study a lot of innovative engineering ideas and thoughts have studied before arriving at general layout and its technological requirements. Following factors are considered while planning and designing Blanket Wall:

- Space constraints
- Type of terrain
- Soil conditions
- Area subjected to heavy rainfall,thick fog considerations
- Transportation of heavy machineries &equipment
- Time factors with respect to project schedule achieving the cost economy &various related aspects.

Keywords: Terrain; Protection; Innovative; Quality; Safety & Economy.

INTRODUCTION

The ‘RCC Blanket Wall’ is required to be constructed for the protection and ‘safety’ of the adjoining existing structures. This type of structure is mainly constructed for the existing elevated natural terrain conditions or series of mountainous hilly area ranging to a high altitude/ +1800 meters.

The blanket wall can be easily constructed without any deep excavation.

In case of conventional construction methods retaining walls are constructed to withstand the earth pressure in the hilly terrain. The foundation part of the retaining wall is deeper& base width as per required design governed by the soil conditions. It would be difficult to design and construct a retaining wall with space constraints specially to accommodate foundation depth due to terrain condition. In the Course of this larger area of space provision to be planned, this may impact on cost & time.

Irrespective of the terrain/profile conditions, the blanket wall can be adopted to safe guard the existing terrain. In case of steep slopes at an angle up to 70 degree the blanket wall shall be adopted after trimming/dressing the profile wherever necessarily called for benches forming to a minimal bare width depending on the profile availability.

The Blanket wall is an art of design and the peripheral end need to be provided with key beams (also called as grip/anchor beams.) At the bottom most level of the blanket wall a conventional drainage system is provided. The thickness of RCC blanket wall varies between 50 mm to 100mm with nominal reinforcements. Weep holes are provided depending on the site conditions especially at lower elevations. The weep holes are located at road drainage and formation level to a height of at least 4meters.

The embedded ‘U’ shaped reinforcement bars are provided to enable access for maintenance activities during emergency situations.

To quote as an example, the blanket wall shown in the pictures has been designed and constructed in a hilly terrain to an altitude of +1120 meters with respect to primary crusher at +1090 meters (30 meters height.)

This blanket wall was constructed 22 years ago and is structurally firm/intact and stable even today. The Blanket Wall has its own merits and advantages compared to vertical walls/retaining walls/reinforced earth retaining wall(RERW)/Soil nailing/other such methods. Most suitably implemented for natural slopped surfaces. It has more advantages than limitation, the cost aspects are also dealt with comparatively very economical to above said methods.

Figures 1, 2, 3, 4, 5 & 6 be referred.

Figure 1. Front view of Blanket wall

Figure 2. Front view of Blanket wall benches

Figure 3. view of Blanket wall at primary crusher entry

Figure 4. Side view of Blanket wall

Figure 5. Side view of blanket wall with key beam & drain

Figure 6. NMDC Project office, Protection Works

Purpose of Blanket wall

‘Blanket Wall’ serves as surface protection to the ad-joining existing units, keeping in view its vicinity to hill, elevated altitudes, space restrictions to provide retaining wall, cost aspects due to wider spread area with close proximity to varying site profile & other many such related. The blanket wall is generally treated as one of the protections to hilly terrains instead of other methods.

Procedure adopted

The ‘Blanket Wall’ is usually spread at a single stretch of length 50 meters&sloping height of 70 meters.

Considering the existing/prevaling site conditions in a hilly terrain area, where crushing plant was built to a height of 30meterswith respect to the start of downhill conveyor. The Dumper Platform (DPF)is at an elevation of +1120 meters. The mountainous terrain in between dumper platform and start off downhill conveyor; was retained/undisturbed (For which the blanket wall protection was adopted.)

The existing contours of the hill have been physically-surveyed and plotted on the drawing in **Fig. 7** as shown below.

Fig. 7. Plan of blanket wall

Based on the contours the location of the dumper Plat-form,primary crusher,secondary crusher,transfer houses, downhill conveyors,silos, screening plant (wet circuit system),loading plant, road/approaches and all the concerned units connectivity requirements have been marked;to accommodate the required size of the plant buildings based on technology of the mining process right up to loading plant.

The level from DPF (Dumper platform) at +1120 meters to loading plant at +550 meters being RHT (Rail Head Top.)that is units are housed to a height of 570 meters in mountainous strata.

Keeping in view the ‘safety’ of all technological units;a decision has been taken to protect the road leading to entry at primary crusher/start of downhill conveyor system.

The base for blanket wall is designed along with the road drain to induce gravity by weight in the form of a beam, to enable blanket wall spring from the beam top. The cross section of the blanket wall shown in **Fig. 8**.

Fig. 8. Cross section of blanket wall

The design of creating gravity beam is to serve the following multiple purposes:

- As a structural member & a part of drain.
- Solid coverage & protection between road & hill part.
- To enable safe movement of heavy moving trolleys/equipment/machinery/other such.
- Envisage Kerb on the outer drain wall supplementing mines safety.
- Also to cater branch to blanket wall.

Key/edge beams: This shall be provided all along the periphery of the blanket wall. The size of key beams generally ranges with width between 200 mm to 250 mm and depth around 400mm. Refer **Fig. 9** for further details.

Fig. 9. Reinforcement details of gravity beam & Blanket wall

At the exterior end of the key beam; fill the extreme cut portion, adjacent to key beam with available boulders & interstices with good earth/morrum. At the meeting point of two different stretches of the blanket walls an expansion joint of width 30mm to be provided. This gap of 30mm is filled with twisted jute impregnated in hot bitumen.

While making blanket wall the trees of any girth can be retained. The required space around the tree is provided with key beams. Before laying the blanket wall the ‘construction paper/polythene sheet’ is provided on the hill profile surfaces before placing the reinforcement. The uniform top surface to the extent possible need to be maintained while laying the concrete.

The thickness of blanket wall concrete due to the existing hill profile varies. Maintain minimum of 50mm thick at any given cross sectional point.

Provide 10mm diameter or 12mm diameter reinforcements in the blanket wall including the key beams to enable flexibility while matching existing terrain/profile conditions. U-shaped bars with 10mm diameter are reinforced as steps which will be used for maintenance activities or at emergency situations.

Quality & Safety Aspects

Quality: Best efforts required to be exercised in all respects to quality aspects, strength of concrete, grade of cement, grade of steel all such related as per IS.

Safety: All precautionary and care need to be implemented as the hilly terrain contours may abruptly vary during construction activities. Prolific experience & expertise will be an added advantage in handling such challenging works.

Cost Aspects

In General with all aspects & considerations no comparison for a blanket wall is drawn with respect to retaining wall/Soil nailing/reinforced earth retaining wall (RERW)/other such. All the said methods are heavily reinforced. However on a broad concept considering the use of nominal reinforcement (excepting the gravity beam), the blanket wall is around 25 percent of other said methods.

Benefits & Limitations of Blanket Wall

Benefits: It has many advantages in comparison with other types of protection works. The listed below are the advantages.

- Faster commencement of work.

- Less involvement of materials, labourers and earth equipment.
- Minimum involvement of the vegetation removal, bigger girth of trees can be retained, unless otherwise demanded by safety considerations.
- Helps in retaining trees and thus partly contribute towards environmental protection.
- Protection to natural drain in valley spots.
- Envisage easy making of benches suiting to site conditions.
- The gravity beam is clubbed along with drainage part.
- Less utilization of steel & minimum grade of concrete.
- Retention of natural terrains without much disturbance.
- 'U' shape rings/steps provided for safety to-wards the maintenance to reach at top point of elevations, also; it will be further useful for works continuity.
- Less maintenance.

Limitations: The listed below are the limitations.

- The Protection is extended for slopes less than/within 70 degree angle of inclination to natural hill.
- This can be adopted as protection to valleys portion where natural water stream flow all time.
- Protection to downstream check dams.
- Effectively made use for capping methods.

ACKNOWLEDGMENT

The Author would like to thank:

- (i) "MECON Limited & NMDC Limited". The Blanket Wall was designed at project Deposit No.10 & 11A, Bailadila Chhattisgarh, Suiting to Project requirement, client NMDC got this executed by renowned executing agencies under the challenging situations; keeping in view the safety of all adjacent existing structures/units during the year 1992 to 2001.

Wind Pressure Distribution over Solar PV Panels Mounted on Pitched Building Roofs

Ashish Agarwal*, Hassan Irtaza, Azhar Jameel

Department of Civil Engineering, Zakir Hussain College of Engineering & Technology, Aligarh Muslim University, Aligarh

*✉ ashishagarwal.ce@gmail.com

ABSTRACT

In the 21st century, transition from non-renewable to renewable energy sources taking place at rapid pace. Within last few years major world economies have shifting to solar and wind energy sources at large scale to meet their energy demand. The government of India has also aimed to reach 100 GW of solar energy installation by 2022 under National Solar Mission, out of which 40 GW is to achieve through rooftop solar. A significant portion of rooftop solar will be installed over pitched building roofs. The pitched roofs are most widely used for buildings in the mountainous region and for industrial buildings. Solar PV arrays are vulnerable under wind-induced loads, and several damaging incidents of have been reported in recent years. Due to the lack of design guidelines and standards, for safe design, wind pressure coefficient over solar arrays mounted on the pitched roof cannot be predicted accurately. In this study, wind pressure coefficients have been determined for solar arrays mounted on hip and saw type building roof subjected to normal (90°) and inclined (45°) wind incidences. Pitch angle considered for hip type and saw type building roofs were 20°, 30°, and 40°. Computation Fluid Dynamics (CFD) technique has been used to determine wind pressure coefficients over solar PV arrays mounted on low rise pitched roof buildings. Reynolds Averaged Navier Stokes (RANS) equations were incorporated in the second-order RNG k- ϵ turbulence model to predict the airflow behaviour through pitched roof buildings and solar arrays mounted on it.

Keywords: Pitched roof; Hip type building roof; Wind pressure; CFD; RANS.

INTRODUCTION

With the technological advancement in the last two decades of the 21st century, the cost per watt installation of solar panels has reduced drastically. Both developed and developing countries are shifting towards solar energy at a rapid pace. Recently, in China and India, Solar energy installation overtook other new installation of renewable or non-renewable energy generation units. India has aimed to reach 100 GW solar installed capacity by 2022 and further raised target to achieve 450 GW of total renewable installed capacity by 2030. As of October 2020, the total installed capacity of solar energy has reached 36 GW, out of which rooftop solar is just 6 GW [1]. Under National Solar Mission, India has aimed to reach 40 GW installed rooftop solar by 2022. The ambitious aim to achieve 40 GW rooftop solar can be done by the installation of solar arrays over unused rooftops of industrial units, factories, and mills. With the cost reduction of solar panels and Li-ion batteries for energy storage, major industries are moving ahead to install rooftop solar systems for energy cost reduction. [2]. India lies between equator and tropic of cancer, and blessed with high solar irradiation throughout the year. Solar array mounting over pitched roof in mountainous region can impart huge potential since pitched roof are common practice in large region in India including Himalayan region and western ghat region. Target to achieve the 40 GW roof mounted solar installation, mountainous buildings with pitched roof can play important role in roof-top solar installation. This ambitious target would incur high capital resources, and any flaw in the solar system at large scale would lead to a huge investment at stake. Solar arrays are vulnerable in wind-induced loads and many past incidents showed damages of rooftop solar arrays at large scale. One such incident was in which wind gust blew off rooftop solar panels mounted on the pitched roof in Buetzow, Germany at wind speeds of up to 119 km/h (6 May 2015) as shown in **Fig. 1** [3].

Cyclone Hudhud has blown away the rooftop solar PV panels in Visakhapatnam at approximate wind speed 160 km/h (October 12, 2014). 12 kW rooftop solar PV array system consisting of 120 panels, out of which 65 were damaged. While solar arrays are vulnerable under wind loads, but still there are very few or no guidelines in any international design codes, including ASCE/SEI 7-10 [4]. Most of the manufacturers and designers rely on conventional codes to determine wind-induced forces on solar array while considering solar array as a mono-slope roof. This approach could not precisely predict the wind load acting on solar arrays/panels and would cause damage to PV panels under wind-induced loads.

Aerodynamic behaviour of solar arrays has been studied both in wind tunnel experiments and numerical simulations by various researchers. The study of PV arrays by various researchers can be divided into three sub-groups, ground-mounted PV arrays, flat roof-mounted PV arrays, and pitched roof-mounted PV arrays. Kopp et al. (2002) [5], Chung et al. (2008) [6], Shademan & Hangan (2010) [7], Bitsuamlak et al. (2010) [8], Jubayer et al. (2011, 2014) [9], [10] and Irtaza et al. (2018) [11] worked on ground-mounted arrays using wind tunnel experiment or CFD simulation or both. Kopp et al. (2012) [12] and Stathopoulos et al. (2014) [13] worked both on flat roof-mounted and ground-mounted arrays. Most of the previous roof-mounted studies were focused on PV arrays mounted on flat roof (Banks (2013) [14]; Geurts et al. (2002) [15]; Kopp (2014) [16]; Stathopoulos et al. (2014) [13]; Wood et al. (2001) [17]).

Fig 1. Damaged solar panels due to high wind over the hipped roof [3]

Ginger et al. (2011) [18] performed wind tunnel tests on flat roof and gable roof buildings (1:20 scaled models) in the wind tunnel test facility at James Cook University, Australia. Pitch angles of gable roof considered were 7.5° , 15° , and 22.5° . The findings from this study were adopted by AS/NZS 1170.2:2011 (AS/NZS, 2012). PV panels of size 1 m x 1.7 m were installed parallel to the gable roof surface and number of tests were performed by changing the size of array (1.7 m x 7 m & 3.4 m x 7 m), location of array on the roof, clear distance between panel and roof surface (0.1 m and 0.2 m) and wind incidence angle. It was observed that the roof pitch angle, panel tilt angle and location of the panel on roof considerably affect the wind pressure over the PV arrays, whereas clear distance and size of the array do not have any significant effect on wind forces over the arrays.

Erwin et al. (2012) [19] investigated wind pressure over PV panels mounted on low rise building roof using full-scale test at Wall of Wind (WoW) research facility, Florida International University, and 1:12 scaled tests were performed using boundary wind tunnel test at RWDI. In this study, single PV panel of dimension 0.95 m x 1.58 m was mounted on the flat roof having tilt angle 0° , 15° , and 45° , and gable roof model at 0° and 15° tilt angles. A good agreement between the small and full-scale results was found for 45° tilted panels.

Geurts and Blackmore (2013) [20] performed field tests on 1 m x 1.5 m single PV panel mounted parallel on the pitched roof of an actual building having pitch angle 42° and compared findings with 1:100 scaled model using wind tunnel tests. Five different clearance distances (0.025 m, 0.05 m, 0.1 m, 0.2 m, and 0.3 m) were tested for a scaled model in a wind tunnel. Relatively small effects on wind pressures over the PV panel was observed on varying the clearance distance.

Aly and Bitsuamlak (2014) [21] performed wind tunnel tests on 1:15 scaled gable roof models having pitch angle 14° (1:4) and 18.3° (1:3). Building dimensions considered were 18.20 m x 9.05 m in plan and 4.27 m roof height, at full-scale. Three different panels of full-scale size 1.5 m x 0.9 m, 1.5 m x 2.4 m, and 1.5 m x 2.7 m were used in wind tunnel experiments. PV panels were mounted parallel with a pitched roof on both sides of the gable. From the results, it was found that wind pressure over PV panels affected both by pitch angle of gable roof and location of the panel on the roof.

Stenabaugh et al. (2015) [22] investigated the aerodynamic effect on PV arrays mounted on a 1:20 scaled model of low-rise buildings having a flat roof and gable roof, using wind tunnel tests at the University of Western Ontario. Several combinations of clearance distances and the gap between modules were examined. The effect of the solar PV panel tilt angle was not considered in this study. From this study, it was found that the small clearance distance and the large gap between panels lead to a smaller net force coefficient on PV panels.

Model Configurations & CFD Simulation

The objective of the current study is to determine wind pressure coefficients over PV panels mounted parallel to hip-type and saw-type industrial building roof having a varied pitched angle from 20° to 40° at an interval of 10° . CFD simulations were incorporated using ANSYS Fluent 18 software [23]. The dimension of hip type building in the plan was 7 m x 14 m. Solar PV

panels are mounted on both side of pitched roof along longer dimension of building in plan. 12 PV panels were mounted in both windward and leeward pitched roof as shown in **Fig. 2**. The dimension of saw type building in the plan was 8 m x 20 m and the height of the building at the windward face was 6 m. Solar arrays mounted over saw type industrial building roof consisting of 6 PV panels (1 m x 2 m) over each 4 pitched roofs of saw type building, as shown in **Fig. 3**. Building and solar arrays mounted over its pitched roof were subjected to the turbulent wind having wind incidence angles of 45° and 90°, as shown in **Fig. 3**. Reynolds’s average Navier Stokes equations were incorporated in the Renormalization Group (RNG) k-ε turbulence model. The following are the governing equations used in the RNG k-ε turbulence model.

$$\frac{\partial(\rho k)}{\partial t} + \text{div}(\rho k U) = \text{div}[\alpha_k \mu_{eff} \cdot \text{grad}(k)] + \tau_{ij} \cdot S_{ij} - \rho \epsilon$$

$$\frac{\partial(\rho \epsilon)}{\partial t} + \text{div}(\rho \epsilon U) = \text{div}[\alpha_\epsilon \mu_{eff} \cdot \text{grad}(\epsilon)] + C_{1\epsilon}^* \frac{\epsilon}{k} \tau_{ij} \cdot S_{ij} - C_{2\epsilon} \rho \frac{\epsilon^2}{k}$$

$$\text{and, } \tau_{ij} = -\rho \overline{u'_i u'_j} = 2 \mu_t S_{ij} - \frac{2}{3} \rho k S_{ij}$$

$$\text{where, } \mu_{eff} = \mu + \mu_t, \quad \mu_t = \rho C_\mu \frac{k^2}{\epsilon}$$

$$\text{and } C_\mu = 0.0845, \quad \alpha_k = \alpha_\epsilon = 1.39, \quad C_{1\epsilon} = 1.42, \quad C_{2\epsilon} = 1.68$$

$$\text{and } C_{1\epsilon}^* = C_{1\epsilon} - \frac{\eta(1 - \eta/\eta_o)}{1 + \beta\eta^3}, \quad \eta = \frac{k}{\epsilon} \sqrt{2S_{ij} \cdot S_{ij}}$$

$$\eta_o = 4.377, \quad \beta = 0.012$$

1:50 scaled industrial building model with PV panels placed parallel over a pitched roof, within the computational domain was modeled in Gambit 2.4.6., commercial modeling and meshing software. The core domain having building was discretized using unstructured mesh by 3D tetrahedral elements, whereas the outer domain was structurally meshed using hexahedral 3D elements. The atmospheric boundary layer was used as a velocity inlet in the computational domain. The inlet velocity profile considered was based on field data of Texas Technical University. Log law atmospheric boundary layer equation taken is as follows.

$$U_z = \frac{u^*}{k} \log\left(\frac{z + z_o}{z_o}\right)$$

where, u* = friction velocity, k = von Karman constant = 0.41, zo = roughness length

Friction velocity u* considered 0.539 m/s and roughness length 10 mm at full scale. Inlet velocity at height 10 m was 10 m/s in the ABL velocity profile. The turbulent intensity and length scale provided in the simulation was 15% and 0.45 m based on field data from Texas Technical University [24]. The base of the computational domain was defined as a rigid wall, and standard boundary function was provided with prismatic elements. Pressure outflow was provided at the outlet of the computational domain.

Fig. 2. Wind incident (90° and 45°) on solar array mounted on hipped roof building

Fig. 3. Wind incident (90° and 45°) on solar array mounted on industrial building with saw type roof

RESULTS & DISCUSSION

Variation on net pressure coefficients over each PV panels mounted over hip type building roof in both windward and leeward roof slopes and subjected to 45° and 90° wind incidences, are shown in **Fig 4**. Pressure coefficient contours over top surface of PV panels mounted on windward and leeward sides of hipped roof are shown in **Figs 7** and **8** for each roof pitch angle in both 45° and 90° wind flow directions, respectively.

Similarly, variation of pressure coefficients over PV panels mounted over saw type industrial building roof in **Fig 5** subjected to 45° wind incidence are shown and in Figure 6 subjected to 90° wind incidence are shown for each roof pitch. Pressure coefficient contours over top surface of PV panels mounted on saw type industrial building roof are shown in **Figs 9** and **10** for each roof pitch angle in both 45° and 90° wind flow directions, respectively.

PV panels subjected to 90° wind incidence, maximum suction pressure found to be increasing with the increase in roof pitch angle for both hip type and saw type building roofs.

Maximum suction observed on PV panels in array 2 for each roof pitches for the saw type buildings. Suction pressure over array 1 decreases with the increase in pitch angle. For 45° wind incidence, maximum suction occurred at panel 1 (near leeward longer side of the building) in array 2 and 3 for all 4 roof pitch angles considered.

Variation in pressure over PV panels with the change in pitch angle does not show any definite pattern when arrays are subjected to 45° wind incidence. For the 40° pitched roof, positive pressure was observed along with PV panels in array 1, when subjected to both 45° and 90° wind incidences. On increasing roof pitch angle, the first sloped roof of saw type building crossed the wake region above it formed by hindrance provided by the windward wall.

Fig. 9(c). Pressure contour over solar PV panels mounted on 40° pitched saw type industrial building roof subjected to 45° wind incidence

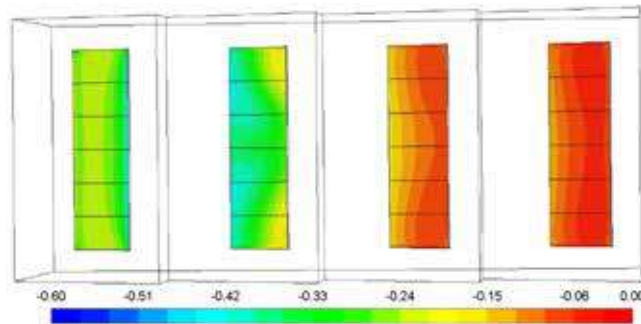

Fig. 10(a). Pressure contour over solar PV panels mounted on 20° pitched saw type industrial building roof subjected to 90° wind incidence

Fig. 10(b). Pressure contour over solar PV panels mounted on 30° pitched saw type industrial building roof subjected to 90° wind incidence

Fig. 10(c). Pressure contour over solar PV panels mounted on 40° pitched saw type industrial building roof subjected to 90° wind incidence

CONCLUSION

- Pressure coefficient over PV panels, mounted over windward pitched roof for hip type building and first array for industrial saw type building, increases with an increase in roof pitch angle subjected to both 45° and 90° wind incidence.
- Pressure coefficients of PV panels mounted over leeward roof in hip type and saw type roof, decrease to higher suction with the increase in roof pitch angle in both 45° and 90° wind incidence.
- On varying wind incidence for 30° pitched roofs, maximum suction was observed over panels in array 3 and array 4 under 45° wind incidence.
- Maximum suction pressure was found over PV panels in array 2 when subjected to 90° wind incidence for all three pitch angles of saw type roof building.
- Solar PV panels mounted on pitched building roof, wind load advisable to design for maximum pressure observed on the individual PV panel mounted over the building roof.

ABSTRACT

Tunnels and underground structures are playing significant role in solving space congestion problem of urban-transportation and sustainable development of the city. The increasing need of underground structures in transportation system is the main reason for studying design and construction methodology of underground structures in very rapid and cost-effective way. Therefore, it is necessary to have an innovative practice on design/construction methodology with realistic consideration of actual site conditions. Also, an innovative technical solution in design/construction might save a project from a deadlock condition arising due to site constraints and other issues. A cut & cover box tunnel section of Lucknow Metro project has been taken for present case study. As per alignment plan, some portions of tunnel infringed with few columns of the portico of a building existing at site. Due to site restriction, an alternative unconventional design/construction methodology was adopted by introducing pile, strut-waler and lattice-girder support systems to construct the cut & cover box tunnel partly irregular in shape without dismantling the existing portico structure. Structural Design/stability and ground deformation have been checked by developing numerical model compared with available analytical solutions. Concept of the present case study may be helpful for the practising engineers in the design of cut & cover tunnels.

Keywords: Underground Structure, Cut & Cover Box Tunnel, Construction Methodology.

INTRODUCTION

The tunnelling and underground structures are nowadays gaining popularity in urban transportation system and other utilities due to the limitations in movement of transportation as well as the restriction in wide expansion of surface infrastructure. Almost every developing city in our country is currently planning to construct tunnels and underground structures for rails, roads, metros, subways and other utilities as well as sustainable development of the city. The growing necessity to expand the urban transportation networks is the main motive for studying the construction and design methodology of underground structures in a very rapid and cost-effective way. And, therefore, it is essential to have an innovative practice on construction and design methodology for such underground structure with realistic consideration of actual site-specific conditions. Also, an innovative technical solution for site-specific design and construction methodology might save a project from a deadlock condition arising due to site constraints and other unwanted issues.

In the present study, a cut & cover box tunnel section of Lucknow Metro North – South corridor has been considered for analysis and discussion purpose. As per tunnel alignment plan of North – South corridor, some portions of a cut & cover box tunnel had infringed with four columns and foundation of building-portico existing at site. Due to site and space constraint, an alternative unconventional design and construction methodology were adopted by introducing RCC Pile, structural steel member strut-waler and lattice girder support with shotcrete systems to construct the cut & cover box tunnel partly irregular in shape without removing and dismantling the existing portico structure at site. Structural stability of the proposed structure and safety of the existing adjacent structures were main key purpose of these innovative and unconventional methodology. Design and construction concept of the present case study may be helpful to practising engineers in the design of tunnels and cut & cover structures.

LOCATION, SITE DETAIL SAND SUB SOIL PROFILE

The line LKCC-06 of Lucknow metro extends from underground ramp (near Charbagh Metro Station) to end of underground

ramp (near K D Singh Babu Stadium metro station) on North – South corridor of Lucknow MRTS, Phase-1A project at Lucknow, Uttar Pradesh, India. Entire project corridor is situated on busy road and clustered building area. As per tunnel alignment, some portions of a cut & cover box tunnel had infringed with four columns and foundation of the portico of a building existing at site. A plan illustrating the cut & cover Box Tunnel (Diaphragm Wall Panels) affected due to infringement of column and foundation of existing portico is shown in **Fig. 1**.

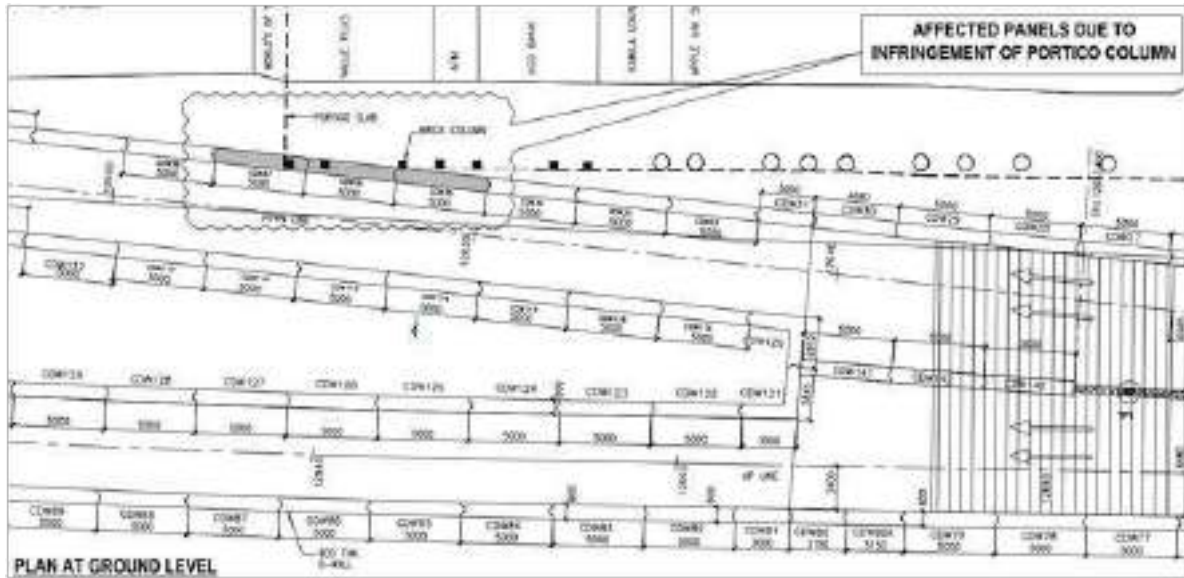

Fig. 1. Plan showing cut & cover Box Tunnel (Diaphragm Wall Panels) affected due to infringement of column and foundation of existing portico of a building

Sub-soil data of concerned location with description for different stratum is shown in **Table 1**. During sub-soil investigation actual water table was observed at 28m below ground level. Also, water level was not encountered during excavation for the entire cut and cover box structure.

Table 1. Geotechnical parameters for different stratum

Ground Condition	Soil Type	Depth, m	SPT Value (Avg.)	Φ' (Avg.) deg	Bulk Density (Avg.) kN/m^3
Top Soil	Made up Ground	0 – 3	-	26	18.0
Stratum - I	Loose to medium silty fine sand	3 – 8.5	20	30	19.0
Stratum - II	Medium to dense silty sand	8.5 – 10.5	35	32	19.0
Stratum - III	Hard Sandy Clayey silt	10.5 – 30.0	30	30	19.0

METHODOLOGY

Due to site constraints and other unwanted issues, partial dismantling or removal of the existing portico structure was not possible during casting of cut & cover box tunnel. Hence, an alternative unconventional construction methodology had been adopted to execute the cut & cover box tunnel without removing / dismantling the existing portico structure. To avoid infringement with column and footing of the portico, cut & cover box tunnel had been cast partly irregular in shape with the help of RCC pile, structural steel members like strut-waler and lattice girder support (steel ribs) systems. **Fig. 2** shows the rearrangement of four Diaphragm wall (D-Wall) panels due to infringement of Portico column-footing. Few D-walls are laterally connected and supported by longitudinal and transverse beams. Cross Section of the rearranged portion of cut & cover box tunnel and a typical portion of cut & cover box tunnel are shown in **Fig. 3**.

Fig. 2. Plan showing the rearrangement of four D-Wall panels due to infringement of Portico column-footing.

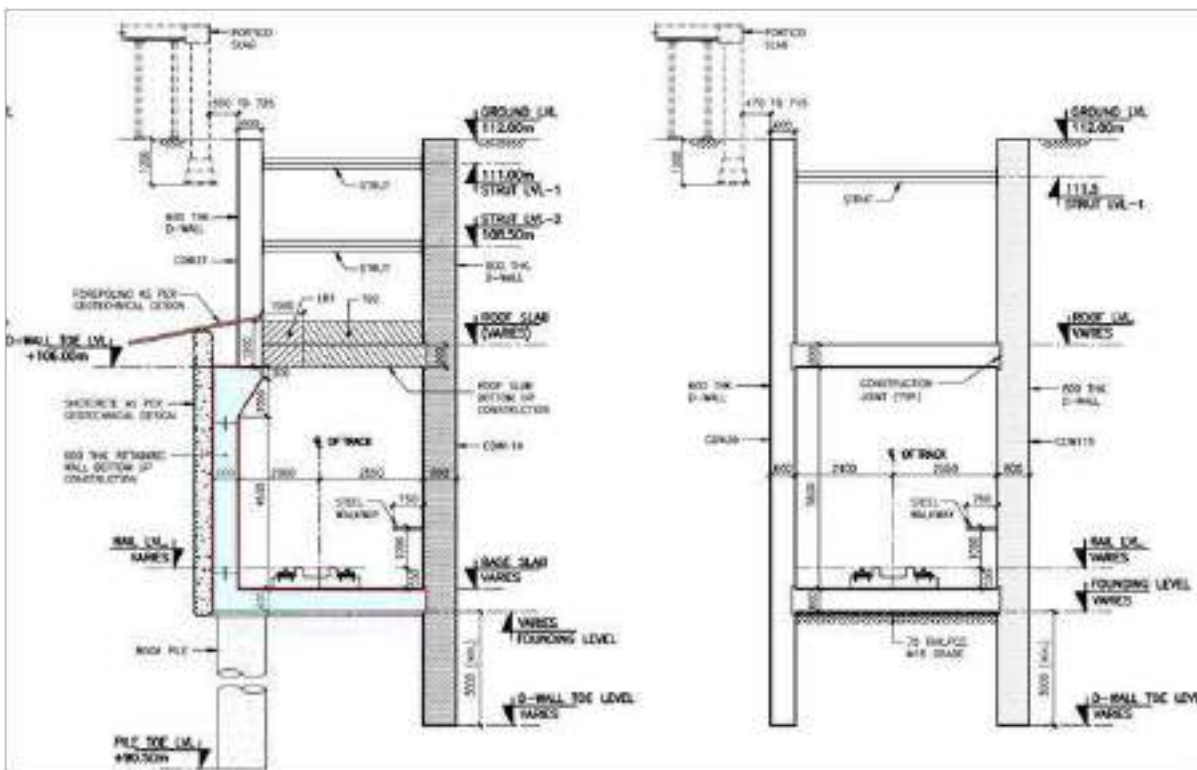

Fig. 3. Cross Section showing the rearranged portion of cut & cover box tunnel (left side) and a typical portion of cut & cover box tunnel (right side).

Stability of the proposed structure and safety of the existing adjacent structures were the main concern of this unconventional methodology and it had been ensured at every stage of the entire construction period.

Construction Methodology

As per construction sequence, the entire casting period had been sub-divided into four different stages of construction which

is partially top-down and partially bottom-up. In first stage, one full-height Diaphragm wall (D-Wall) and one half-height Diaphragm wall (resting on RCC bored pile with a diameter of 800mm) had been cast to serve the purpose of temporary as well as permanent earth retaining structure. Two level of temporary steel strut-waler had been used for supporting excavation till the soffit of top slab of the box tunnel. In second stage, two transverse beams and one longitudinal beam had been further cast along with casting of top slab of box tunnel. These beams ensured the lateral stability and interconnectivity between all rearranged D-Wall panels. Forepoling system had been provided through the half-height D-Wall well before the starting of further excavation below top slab of box tunnel. **Fig. 4** shows excavation done till the soffit of top slab of box tunnel and casting of beams along with top slab of box tunnel.

Fig. 4. Cross Section showing excavation done till the soffit of top slab of box tunnel (left side) and casting of beams along with top slab of box tunnel (right side).

In third stage, excavation had been continued till soffit of bottom slab of box tunnel. A lattice girder support (steel ribs) with shotcrete systems had been provided as part of earth retaining system till the casting of bottom slab and RCC wall. In final stage, bottom slab and connecting RCC wall had been cast. Backfilling and reinstating of road surface had been done after removal of temporary steel strut-waler. **Fig. 5** shows the excavation below top slab of box tunnel and reinstating of road surface after casting and backfilling done.

Fig. 5. Cross Section showing the excavation below top slab of box tunnel (left side) and reinstating of road surface after casting and backfilling done (right side).

Design Methodology

Design methodology has been sub-divided into construction stage analysis, service stage analysis and stability analysis. The structure analysis was done for different loads and combination to obtain the most severe combinations and envelopes of forces (moments, shear force, etc.) on every component of the structure.

Construction Stage Analysis

Construction stage analysis of diaphragm wall was done by using WALLAP [6] & STAAD Pro. [3] software to obtain the effects of lateral load during sequential excavation. Effect due to vertical construction load was obtained by using STAAD Pro [3]. Construction of D-Wall and top slab of cut & cover box tunnel was done by top-down sequence with two level of temporary strut-waler support. Bending moment, shear force and displacement envelope of the D-wall from WALLAP analysis are shown in Fig. 6.

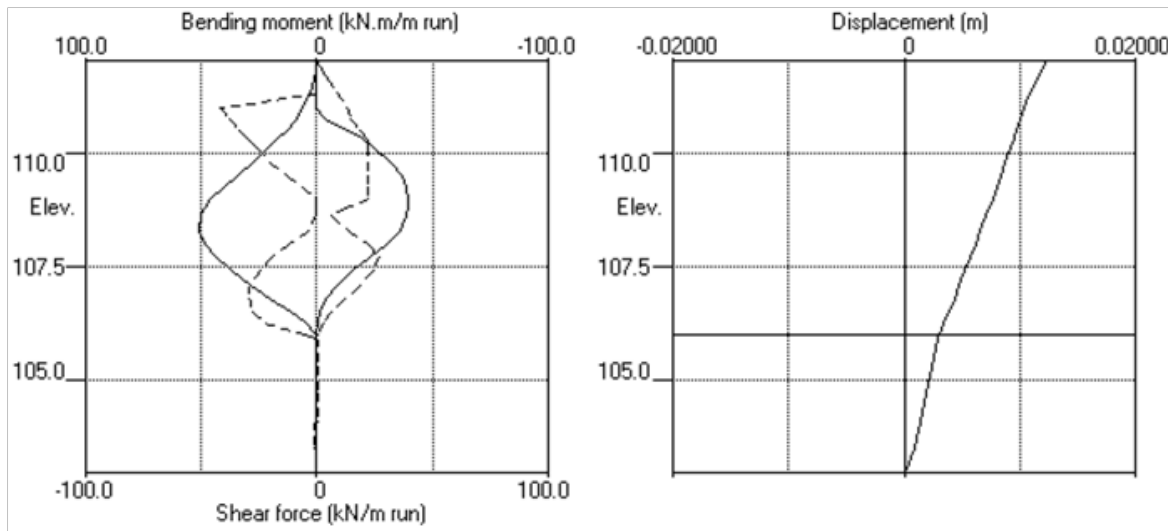

Fig. 6. Bending moment, shear force and displacement envelope of the D-wall from WALLAP analysis

Isometric view of the STAAD Pro. Plate 3D model with two levels of strut support and bending moment contour are shown in Fig. 7.

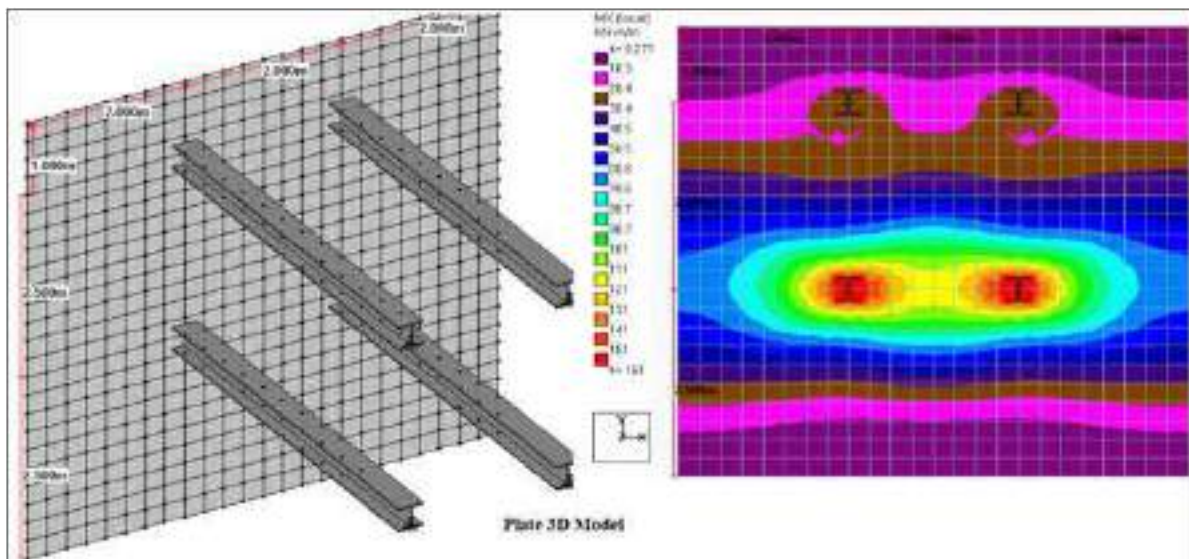

Fig. 7. Isometric view of the STAAD Pro. Plate 3D model (left side) and bending moment contour (right side)

Service Stage Analysis

Service stage analysis for lateral and horizontal loads was done by using STAAD Pro. software. All service stage loads like Dead Load, Superimposed Deal Load, Live Load, Water Pressure and Earth Pressure were considered and suitably combined as per load combination to obtain the most severe combinations and envelopes of forces [2]. Seismic racking analysis with 0.12g(DBE) and 0.24g(MCE) was also performed for the service stage [1].

Stability Analysis

The complete structure was checked against flotation with water table at ground level. Capacity of RCC pile below half-height D-Wall was checked with respect to vertical load at D-Wall tip. A numerical model (finite element method) was further developed to check the ground stability. Input for numerical model (finite element method) with full excavation is shown in **Fig. 8**.

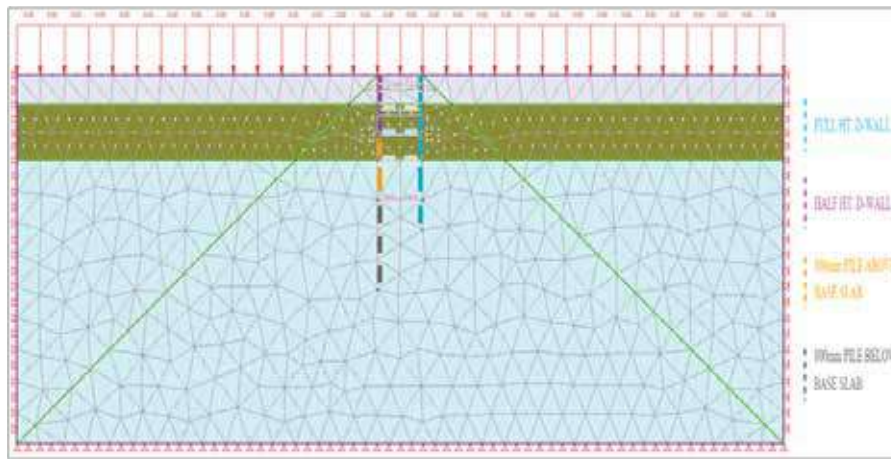

Fig. 8. Input of numerical model (finite element method) with full excavation.

DISCUSSION ON ANALYSIS

As outcomes of numerical model (with full excavation), vertical settlement of ground surface and D-wall along with horizontal displacement of D-Wall were estimated. Ground stability and safety to adjacent structure were ensured by checking ground deformation with respect to its limiting value. Apart from theoretical values, actual site-based ground settlements were recorded and checked during the entire excavation and casting procedure at site. Vertical settlements of ground surface, pile and D-Wall are shown in **Fig. 9**. Horizontal displacements of D-Wall and pile are shown in **Fig. 10**. As an additional precaution, a detailed building condition survey (BCS) on adjacent existing structures was done prior to excavation. Additional protection to the existing adjacent structure had been further provided based on BCS report.

Fig. 9. Vertical settlement of ground surface, pile and D-Wall.

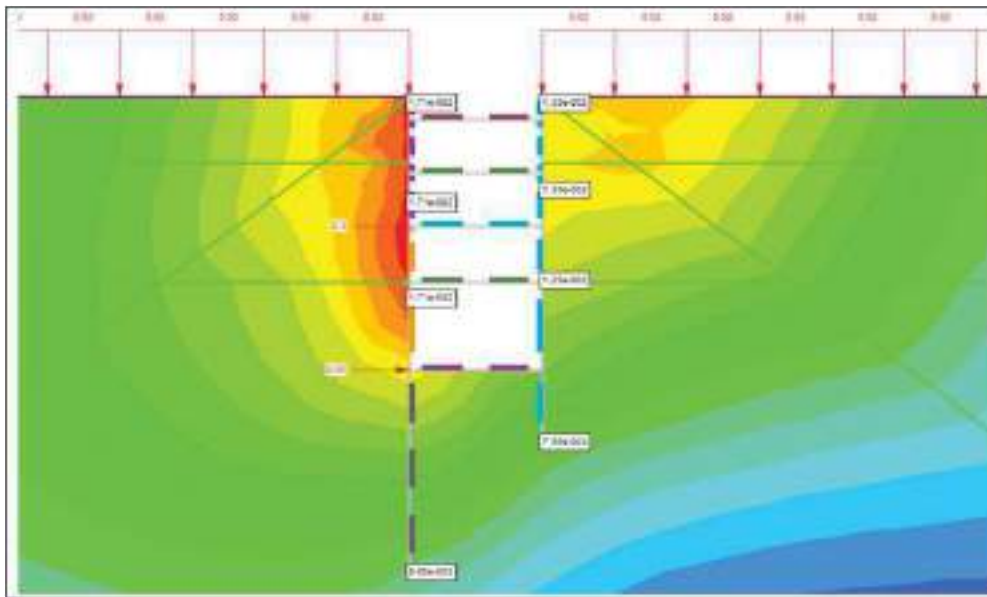

Fig. 10. Horizontal displacement of D-Wall and pile.

Schedule of dimension check for Kinematic envelope and structure gauge was also done for irregular shape of cut & cover box tunnel. Fig. 11 shows schedule of dimension check for Kinematic envelope and structure gauge.

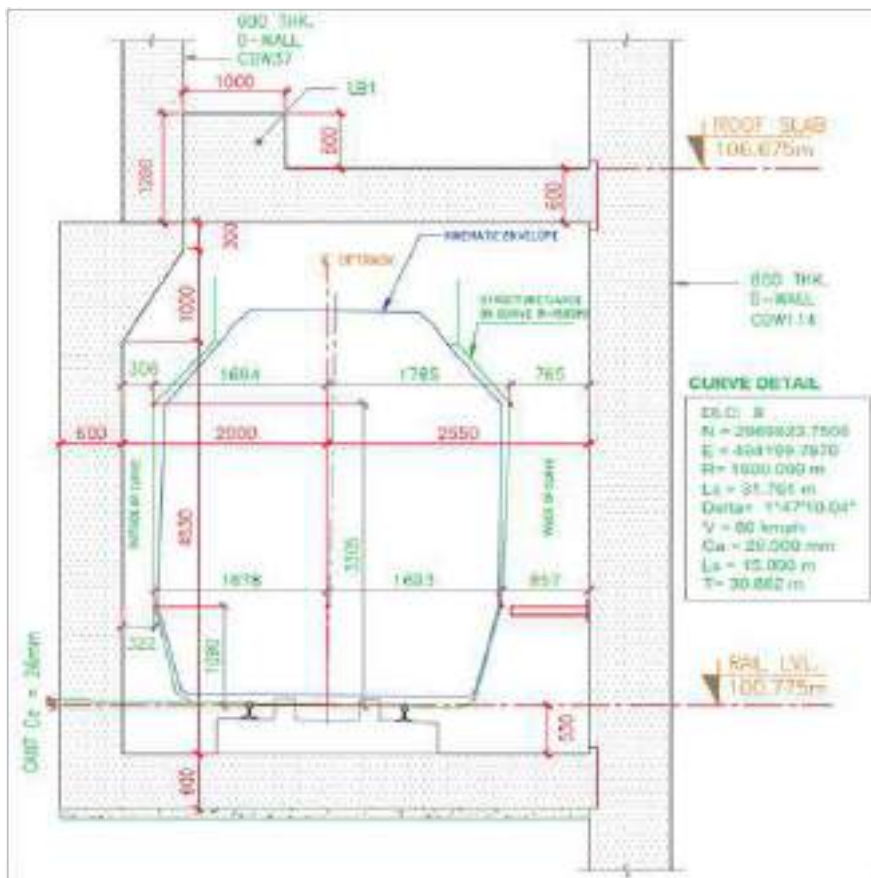

Fig. 11. Schedule of dimension check for Kinematic envelope and structure gauge.

CONCLUSIONS

The present paper describes an alternative unconventional design and construction methodology to construct a cut & cover box tunnel without removing/dismantling the portico of an existing building at site. To avoid infringement with existing building-portico, cut & cover box tunnel had been cast partly irregular in shape with the help of RCC Pile, structural steel members such as strut-waler and lattice girder support (steel ribs) systems. Present innovative solution had been conceptualised, analysed and finalized after exploring of various options related to structural stability of the proposed structure and safety of the existing adjacent structures. Unconventional and innovative technical solution for site-specific issues may save a project from a deadlock condition arising due to site constraints and other unwanted issues. The entire concept of the present case study may be helpful for the researchers and practising engineers in the design of tunnels and cut & cover structures for rails, roads, metros, subways and other utilities.

1D Flood Model to Retrace the July 2018 Flood in Lower Reaches of Pamba River, Kerala

Dr T K Drissia

Surface Water Division, Centre for Water Resources Development and Management, Kozhikode, Kerala

✉ drissia@cwrwm.org

ABSTRACT

Devastating floods occurs every year at some regions of the world, in Indian also. The year 2018 witnessed severe flood in Kerala. This study attempted to retrace the flood event during July 2018, though severe flood occurred is during August 2018, due to the non-availability of observed data. This study used MIKE HYDRO River for developing a hydrodynamic model for the lower reaches of Pamba during the period 1/6/2018 to 14/08/2018. The river stretch considered for the study is the between the Kalloopara in Manimala River, Malakkara in Pamba River and Thumpamon in Achenkovil River and Thottapally spillway. The model calibration was carried out by changing manning's coefficient. At the Pamba, Manimala and Achenkovil gauging stations, the correlation coefficient between the simulated and observed water level is 0.949, 0.879 and 0.799. The flood model give a spatial variation of the flood depth during July 2020. This study helps to understand the flood dynamics and initiates further study on the August 2018 flood.

Keywords: 1D flood model; MIKE HYDRO River; Pamba; Kerala.

INTRODUCTION

Extreme events are frequently occurring in recent years, which destroy life and property. The Kerala Flood 2018 is one such event; the earlier experience of flood in this region is in 1924, almost 100 years back. A one-dimensional model is the simplest way of representing river dynamics, assuming the river along the center line of the river. Literature reported various 1D model for hydrodynamic models. TUFLOW Classic1D, Flood ModellerPro 1D solver, OBEK Suite, MIKE11/MIKE HYDRO River, HEC-RAS are few to name [1]. The one-dimensional hydrodynamic model uses Saint Venon's equation to simulate the flood [2; 3]. The flood vulnerability area of Damodar River, India is studied using MIKE HYDRO River. The model was calibrated with Manning's coefficient and validated with ground data [4].

With these short literature discussed, it is to say that in the past, the flood was not a frequently occurring phenomenon in Kerala, except the Kuttanad region. Because of this, flood-related studies in Kerala is not available much. In this regard, this study evaluates the flood occurred during July 2018 in Pamba river Kerala. Though devastating flood occurred during August 2018, the discharge data is not available. Therefore, to understand the dynamics of the flood, initially, the model was developed for the flood occurred during July 2018.

STUDY AREA

Pamba is the third-longest river in Kerala, with 176km). Manimala River drains in the north of Pamba and Achenkovil converges in the south before joining the Arabian Sea through Thottapally spillway. The annual average rainfall in the catchment of Pamba is 3771 mm, Manimala is 3516 mm, and Achenkovil is 2933 mm (CWRDM, 2017). This study considered the lower reaches of the Pamba River in Kerala, the river stretch between the Malakkara to the Thottapally spillway in Pamba, the river stretch in Manimala River from Kalloopara until it joins Pamba, the river stretch in Achenkovil between the Thumpamon until the confluence point with Pamba **Fig 1**.

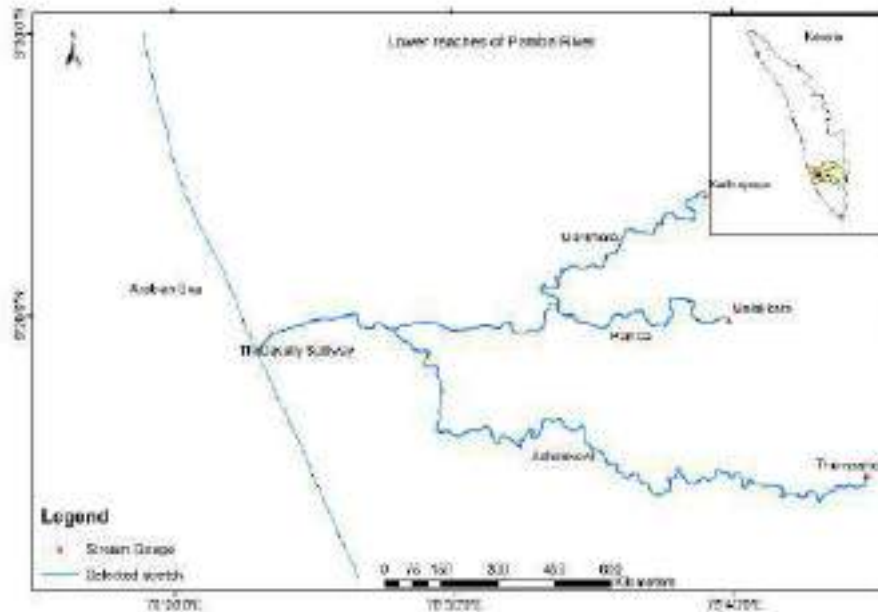

Fig. 1. Location of lower reaches of Pamba

MATERIALS AND METHOD

For the analysis, this study utilised the discharge and water level data of three gauging stations, Malakkara, Kallupara and Thumpamon maintained by Central Water Commission (CWC), India. These are the upper bound of

the study area, the lower bound being the level at Thottapally Spillway. The water level near Thottapally spillway is obtained from the Water Resources Department, Kerala. For developing the flood model, another input required is the river cross-sections. Hydrographic Survey Wing (HSW), Government of Kerala carried out the bathymetry and topographical survey to extract the cross-sections of the streams from the mean sea level. The period analysed were from 1/6/2018 to 14/8/2018, though the most severe flood occurred from 14th to 16th August 2018, as the observed discharge is not available.

The 1D flood model was developed using MIKE HYDRO River developed by DHI. The main governing equation in fluvial hydraulics is Saint Venon's equation, finite difference method. Saint Venon's equation works on the conservation of mass and momentum. The assumptions in the governing equations are the flow is one-dimensional i.e. velocity is constant. Flow is assumed to be gradually varying along the channel. The bottom slope is small, so the effect of scouring and deposition is negligible. The differential form of the equations is as follows.

$$\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = 0 \tag{1}$$

$$\frac{\partial Q}{\partial t} + \frac{\partial}{\partial x} (uQ) + gA \left(\frac{\partial h}{\partial x} - S_0 \right) + gASf = 0 \tag{2}$$

where Q is discharge, A is cross-sectional wetted area, u is longitudinal flow velocity, h is flow depth, S_0 is bed slope, and Sf is friction slope (Chow, 1988). The flood model developed for 1/6/2018 to 14/8/2018 using surveyed cross section.

RESULTS

The 1D model developed using MIKE HYDRO River was for the period 1/6/2018 to 14/8/2018. The MIKE HYDRO River has four modules, network module, cross-section module, boundary condition module and hydrodynamic parameters module. The network module was created, by delineating the river stretch from the CWC gauging stations to Thottapally spillway, after that, chain ages generated for the river stretch. In the cross-section module, we entered the river cross-sections. Boundary condition module requires the upper boundary and lower boundary; the upper boundary condition is the observed discharge at Kallupara, Malakkara and Thumpamon gauging station. The lower boundary condition is the water level near the Thottapally.

In the hydrodynamic- parameter module, we selected the fully hydrodynamic option. Initially, the model is run by taking the default Manning’s coefficient. Then, for the calibration of the model, in the Manimala stream, the Manning’s coefficient changed to 0.03 until chainage 14070m and the remaining 0.035, in Pamba stretch of river, from 0 to 4414, m is taken as 0.04 and remaining is 0.03, in Achenkovil, from chainage 0 to 44261, m is 0.02, until 63130 is 0.03.

The model was calibrated by changing Manning’s coefficient; the evaluation is carried out by the water levels at the three gauging stations. **Figs. 2 to 4** show the calibration graphs of Kalloopara, Malakkara and Thumpamon. In Achenkovil, the flows are under predicted. The simulated water level at Kalloopara and Malakkara show good agreement with the observed data with R-value as 0.959 and 0.973, respectively.

Fig. 2. Calibration graph at Kalloopara gauging station in Manimala

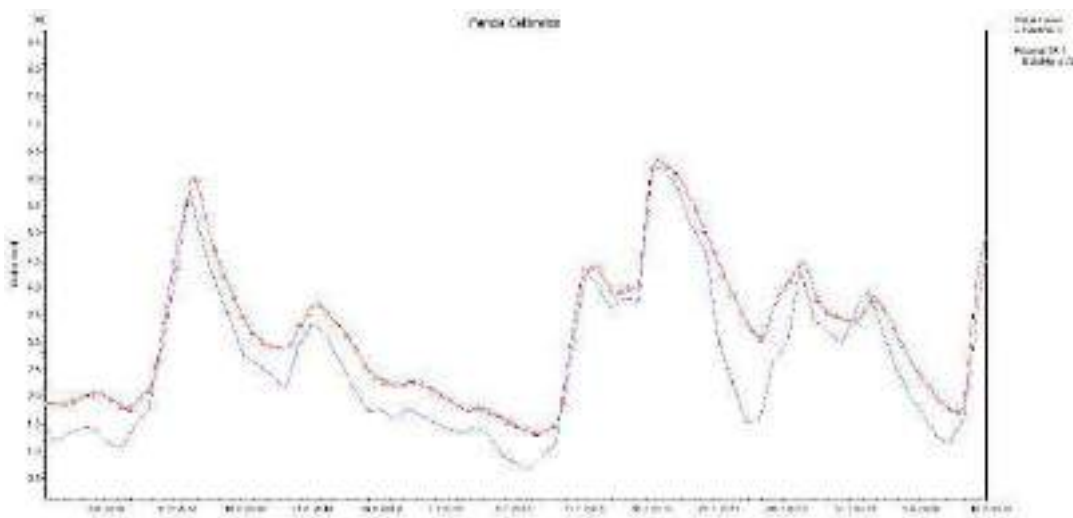

Fig. 3. Calibration graph at Malakkara gauging station in Pamba

Preceding August 2018 flood, a flood occurred during 16-17 July 2018, the peak water level observed is 8.1 m at Kalloopara on 17th July, but the simulated value is about 11 m. In Malakkara, the observed peak water level is 6.215m on 16th July, whereas the simulated water level is around 11 m. The maximum water level observed in Thumpamon during July is 10.76m, in the place of simulated water level of about 10.5m. It is evident from the **Table1**, with peak error as -0.341m and -0.436m and 0.006, respectively for Manimala, Pamba and Achenkovil. The spatial representation of the flood depth at various location between the gauging stations and Thottappally spillway is analysed. **Fig. 5** presents the spatial representation of flood depth. The flood depth at the downstream of Pamba is higher than 3 meter as per the model output on July 17th, 2018. The upper reaches of Pamba and Manimala are not much affected. The model shows the upstream of Achenkovil has a flood depth of 1-2m, but the model prediction has a maximum positive difference of 1.672m (Table 1), and hence the actual flood depth may be less than this.

Table 1. Performance evaluation of the model

Statistical indicators	Manimala	Pamba	Achenk ovil
Correlation coefficient	0.949	0.877	0.799
Peak error	-5.525%	-23.232%	-4.756%
Volume error	-9.34%	-19.329%	5.549%
Max. positive difference	0.342m	0.212m	1.672m
Max. negative difference	-1.072m	-1.882	-1.292m

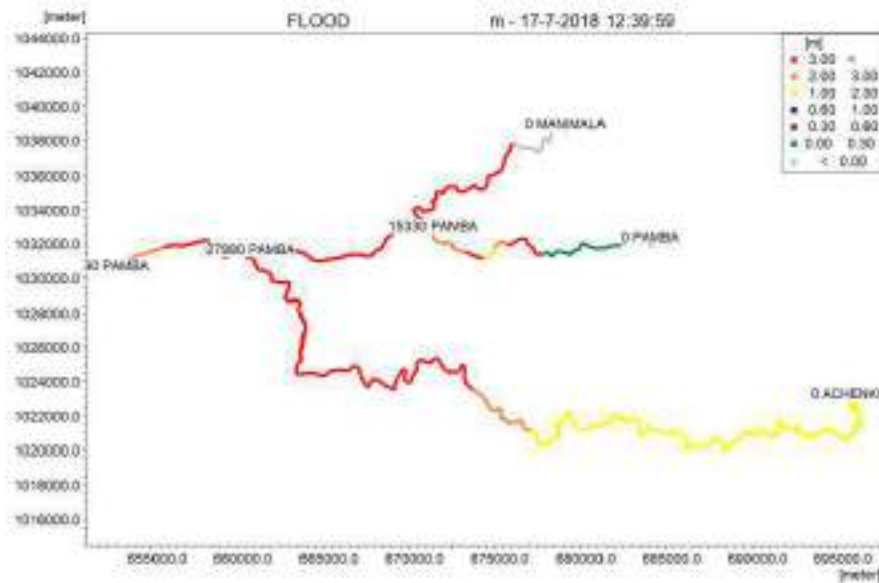

Fig. 4. Spatial presentation of flood depth on 17/7/2018

CONCLUSIONS

The July 2018 flood in the lower reaches of Pamba River Kerala is retraced using MIKE HYDRO River. The calibration with the observed water level at the three CWC gauging stations shows good agreement with the observed values. The peak difference is less than one in Manimala and Pamba River, though slightly more than one in Achenkovil River. This study helps to understand the flood occurred in July 2018 and aids in the further study of August 2018 flood occurred in Kerala.

ACKNOWLEDGMENT

The author thank The Hydrographic Survey Wing, Government of Kerala for carrying out survey work. The Central Water Commission is acknowledged for sharing the data.

ABSTRACT

This propounded literature paper emphasizes a cardinal focus on the elaborative research work proffered on the impact of assorted waste materials in flexible pavement construction. From numerous pieces of literature, it is evident that the neoteric materials fashioning flexible pavements are coir geotextiles, rubber, marble dust, nylon tire cord fibers, which pitch-up to strengthen the soil and also improvising the life span of the pavements, with minimal rutting and cracking distress problems causing a surge in CBR value, and thereby, ameliorating the tensile strength of the bituminous concrete mixes (BC). Furthermore, crumb rubber (CR), Polypropylene, and eco-friendly asbestos fibers, pile up to the genre of enhancing the bitumen binder properties besides being cost-effective. Therefore, this study catalogues the hefty scope in the usage of a differential combination of waste materials in acquiring a high performing sub grade.

Keywords: Geotextile; Crumb rubber; Polypropylene fibers; Tensile strength.

INTRODUCTION

A pavement can either be a flexible or rigid pavement. Flexible pavement comprising of sub grade, sub-base, base, and surface course pavement has lower flexural strength [1] and is pliable in structural action under a higher volume of traffic and load relays the vertical or compressive stresses by grain to grain transfer to the lower layers of soil [2]. An ideal flexible pavement yields elastically to traffic loading. In general, the flexible pavement is devised with a treated bituminous surface or with a fairly thin hot- matrix asphalt surface (HMA) on the sub grade where one or more unbounded base courses rest [3]. The load-distributing characteristics of a layered pavement derive its strength delineated to protect each layer from compressive shear failure in the sub grade. In the present study, combinations of various waste materials used to improve the flexible pavement sub grade are quoted.

STATE OF THE ART

An extensive literature survey has put forth on the use of sundry waste materials in all categories and its effects on flexible pavement construction.

Raji A.K et al (2011) discussed the inclusion of coir geotextile and fly ash in black cotton soil of low CBR value and high pavement distress. An amalgamation of fly ash (5%), cement and reinforced with geotextile (2.5%) at 1000 repetitions is 5.72 mm given as rut behavior. With 28%, CBR has proven to be extraordinary for the soil with improvised design life [4].

Adebayo V.B and Mohammed H (2016) have scrutinized the asphaltic concrete with pulverized coconut fiber (PCF) containing surplus quantity of lignin makes it tougher and stiffer. The Marshall Stability test is done for Asphaltic concrete with PCF in the quantity of 0%, 4%, 6%, 8%, 10%, and 12% by weight. From the results, an optimum rise of 8% is noted in the stability and flow properties of the pavement [5].

Narendra Goud G et al (2017) quoted the inclusion of coir pith and lime in soil, making it a suitable sub grade material by reducing the free swell index (FSI). The Unconfined Compressive Strength (UCS) and the California Bearing Ratio (CBR) tests for soil in combinations of coir pith contents (1%, 2%, and 3%) and lime contents (2%, 3%, and 4%) resulted in a rise of UCS

value by 300KPa to 380KPa after 3 days and 470KPa to 570KPa after 7 days of curing & a rise in the CBR value by 1.04% to 9% [6].

Vijayan A et al (2016) scrutinized composites (coir fiber- latex, woven coir mat, and woven coir mat- latex) as a separator in flexible pavements for its high mechanical strength deliberated by CBR value. It was heeded that the 28th day CBR value of woven coir mat- latex composite was examined to be three times higher than the coir fiber- latex composite and ten times exorbitant than woven coir mat [7].

Nithin S et al (2012) asseverated coir geotextile (CGT) inclusion in the wet macadam mix as a reinforcing material to strengthen the sub grade and witnessed an advancement by 1.61 times in Ultimate Bearing Capacity and have evinced the improvement of greater footing settlement in the load settlement characteristics [8].

Singh R. R and Shelly M (2014) study expounded the effect of coconut coir on soil stabilization with the help of unsoaked, soaked CBR and UCS tests. It is clearly seen that the unsoaked and soaked CBR values have exhibited an increase of 8.72% to 13.55% and 4.75% to 9.22% with an increase in the fiber content. As per the observations, the maximum improvements in UCS values are achieved with an inclusion of 1% of coir to the soil [9].

Mahabir P et al (2013) unraveled the incorporation of VG 30 bitumen, CRMB 60 (modified binder), and non-conventional coconut fiber (natural fiber) which resulted in the huge improvement of the toughness of mixture but the biodegradable nature of these fibers made them inappropriate for longer reinforcement life. Therefore, from the performed analysis, it has been obvious that annexation of 0.3% fiber can overshadow the fatigue life of the mix [10].

T A Balqis (2020) affirmed the inclusion of crumb rubber it is ratified that pavement with CR is found to exhibit lesser tensile strain by 20.6 % and compression strain by 2.9%. Besides the decrease in strain, CR inclusion in the pavements is proven to have enhanced the performance of flexible pavements along with an increased life [11].

Sigit Pranowo Hadiwardoyo et al (2018) discussed the stratagem of revamping the strength characteristics and also truncating building materials in composite materials by the wield of synthetic and natural fibers. As avowed, the tensile strength of fibers is high, and they also have the flair to enhance the asphalt mixture's cohesive nature. In this study, the preferred additives are shortly decorticated pulp coconut fibers. 60/70 asphalt content was taken to which 0.5-1.25cm of short coconut fibers were mixed anticipating 0%, 0.75%, and 1.5% yield. The skid number of asphalt mixture has risen by 19% with the appendage of 0.75% coconut fiber when analogized with virgin asphalt mixture. But the inclusion of fibers did not show any acceptable increase in the resistance criteria with changes in temperature, thereby proving that with a hike in the vehicular count of passes, the resistance falls off [12].

Suresh T et al (2016) manifested that the usage of waste materials in the bituminous pavement is out of harm's way with a more ecological binder for escalating properties of road. This paper deals with the study of the influence of waste materials in the bituminous pavement performance. In appraising the study, bitumen is combined with 1%, 2%, 3%, 4%, and 5% of coir fibers. Marshall Stability test was performed on both normal and modified bitumen. Consequently, it is observed that bitumen with coir fibers intended better durability. Also, the supreme concern of a bituminous modifier is to proliferate the resistance of the asphalt against perennial deformation at high road temperatures besides, maintaining the original bituminous properties unmoved. The inclusion of plastic waste in the modified bitumen has shown a surpassed binding property along with enhanced stability, and density. Therefore, it is writ large that the stability enhancement is more in the case of modified bitumen rather than in the regular bitumen mix. The value of softening also exhibited a slight decrease in the modified bitumen mix [13].

Saravana Selvam V et al (2016) studied the usage of coir fiber (natural fiber) and nylon tyre-cords (synthetic fiber) in pavements. The full-length experimental work was categorized as Phase-1: Index properties determination. Phase-2: Determination of engineering properties. Phase-3: Designing of subgrade pavement thickness as per IRC 37-2001. The fibers are used in the soil sample as additives in the percentage of 0.1%, 0.2%, 0.3%, and 0.4%. Not only the optimum traditional fiber mix but also the expansive clays were also treated with non-traditional bio-enzyme stabilisers. Utilization of Coir fiber, Tyre cord fiber and bio-enzyme in the stabilisation of expansive soil thereby increases strength and reduces the thickness of subgrade. Bio-enzyme is available as a concentrated liquid and is to be diluted with water before mixing with soil which produces cementation action. The dosage of the enzyme is 200ml for 1m³ of soil. The use of bio-enzyme reduces pavement thickness [14].

Priya K. V (2016) discussed the coir fiber reinforced bituminous mixes. To avoid cracking and to improve stability, the

bituminous mix is reinforced with coir fiber along with the inclusion of an anti-stripping agent. Silicon-based Nano-technology termed as the Wet bond is the preferred anti-stripping additive in the asphalt whose thermal resistivity is considerably high, thus making it suitable for hot and warm road designs. One more crucial pronouncement in the area of complex modulus is that the value is noted to have an increase with the rise in content of modified binder and vice versa in the case of the phase angle. The addition of coir fibers has resulted in a two-times more increase in the value of stability. Inclusion of anti-stripping agent “wet bond-SP+” improves the bonding between aggregate and bitumen in the pavement, thus avoiding the stripping problems even in heavy rainy conditions. Polypropylene (PP) fibers were also used in fiber reinforced bituminous concrete for escalating the Marshall Stability value. Eventually, PP fibers abated the flow values [15].

Leema Peter (2020) instigated the use of coir waste as a subgrade material for strengthening the flexible pavements. Soft soil alone is inappropriate material for pavement construction as the occurrence of failure can be noted at the premature age itself. As a counteract, coir waste material is taken into consideration to resist the volume changes of the subgrade soil. Coir waste material, when mixed with soil subgrade, becomes resistive in nature. Consequently, the engineering properties of coir waste material need to be balanced. Thus, the inclusion of lime along with coir waste material as a subgrade filler is introduced. Lime plays the role of a stabilizer with coir waste to balance the low behaviour of soil in terms of compression, undrained shear strength, and deformation criteria. From the experimental analysis, it is evident that the inclusion of coir waste along with lime is handy in constructing a sustainable pavement with reduced thickness and with a cost cut-down [16].

M.C. Jayachandran (2019) exclusively dealt with the study of coir geotextile (CGT) in the flexible pavement as a reinforcing material. CGT is a natural fiber with more cost-effectiveness due to its availability in abundance. This study has given an intelligible comparison between the reinforced and unreinforced CGT pavements. The strength of the pavements is determined using the Dynamic Cone Penetrometer (DCP), and the visual evaluation is done for performance functionality. As per the study, four pavements are tested for strength with a subdivision of pavement with coir reinforcement and pavement without coir reinforcement in each pavement. From the results of DCP, the observed values exhibited the coir reinforced pavement to have retained its stability even after 6 years without any pavement distress. The coir reinforced pavement exhibited a reduction of 20% to 30% in the indices of DCP for a span of six long years provided the strength and stability are comparatively high in the pavement with CGT. Concerning the visual evaluation, the pot-holes were located on the pavement without CGT but for the same time, those are accounted to be absent in CGT pavement. Therefore, conclusions drawn from the experimental analysis states that the life span of coir reinforced pavement is way longer than the conventional type with lessened distresses and deformations [17].

Hayder K. Shanbara et al (2020) emphasized the supreme focus on deterioration of flexible pavements due to lack of significant tensile strength of bituminous mixtures. To achieve the desired strength, incorporation of polypropylene fibers in the bituminous mix is made and thereby, tests are carried out for performance evaluation experimentally. 100/150 penetration grade bitumen binder is employed for mix. Polypropylene fiber of 0.1 mm diameter of unit weight 900 kg/m³ were added to the binder of 1.02 g/cm³ density. For a more accurate outlook, various tests akin to Indirect tensile stiffness modulus, Four-point bending fatigue, Three-point bending tests were performed. Fibers in the percentage of 0.2, 0.3, 0.35 and 0.4 were added to the binder resulting in the development of stiffness modulus by 30%. In addition to the stiffness, polypropylene fiber has lowered the fatigue by 41 % and finally makes the mixture the most desired one than the conventional mix [18]

WASTE PRODUCTS IN THE CONSTRUCTION OF ROADS

The following tabular forms indicate the usage of various industrial waste products used in flexible pavement construction.

Table 1. Industrial waste products suitability in the construction of roads

Waste Product	Source	Possible Usage
Slag from Blast Furnace	Steel industry	Filler material in Bass and Sub-base course, Binders for soil stabilization (ground slag)
Dust from Cement kiln	Cement industry	Base Stabilization & Modified binder in bituminous mix
China clay	Bricks and tile industry	As bituminous mix aggregates & Bulk-fill
Colliery spoil	Coal mining	Bulk-fill
Sands of Foundry	Foundry industry	Bulk-fill, filler for Concrete ,crack-relief layer

Glass waste	Glass industry	Reinforcement of Glass-fiber, bulk fill
Fly ash	Thermal power station	Bulk fill, filler in bituminous mix, artificial aggregates
Marble dust	marble industry	Filler in bituminous mix
Waste tyres	Automobile industry	Rubber modified bitumen, aggregate

(Source: Javed et al., 1994 [19]; Sherwood 1995 [20]; Okagbue et al., 1999 [21]; Mroueh et al., 2002; Hawkins et al., 2003 [22]; TFHRC 2004)

Table 2. Advantages and disadvantages of utilization of industrial waste products in the field of road construction

Materials	Highlights	Challenges
Fly ash	Light weight, its pozzolanic properties made it a good choice as a binder to stabilise base/sub-base	Non-homogeneous, development of strength is a time taking process
Steel Slag	Resistance to skid is relatively high	incompatible for fill work beneath slabs as well as for concrete works
Slag of Blast Furnace	Plays a key role in the manufacturing of cement and granular fill	Leachate formation makes it undesirable and effects groundwater in the form of pollution, used as unbound aggregates
Colliery Soil	-	
	Inevitable unburnt coal combustion, Impact of sulphate attack on concrete roads is not desirable	
Spent oil shale	-	Burning of combustible materials
Cement kiln dust	Hardening can be achieved when moisture exposure is provided. Also a good stabilization material	Percentage of alkalis provokes Corrosion effect on metals (used in concrete roads)
Used engine oil	Makes a better air entraining material that can be utilized in the works dealing with concrete	System of collection of used engine oil is slightly complicated
Non Ferrous Slag	Light weight	May show inconsistent properties
Tailings of Mills	Pozzolanic nature makes it worthy	Presence of undesirable poisonous materials

(Source: Javed et al., 1994[19] ; Sherwood 1995[20]; Nunes et al., 1996[22] ; Hawkins et al., 2003[22]; TFHRC 2004)

CONCLUSION

From The Performed Studies, It Is Evident That The Modified Bituminous Concrete Mixture Of Marble Dust And Coir Fiber Exhibits A High Rise In Tensile Strength When Compared To Neat Mix. The Improvement In The Predominant Strength Property Concerning CBR And Rut Depth Is Determined Through Experimental Analysis Of Soil With The Inclusion Of Waste Materials Like Fly Ash, Cement, And Coir Geotextiles In The Selected Sub Grade. Also From The Investigation, It Is Proven That The Inclusion Of Pulverized Coconut Fiber Can Increase The Marshall Stability Value Of Asphaltic Concrete. Likewise, The Enhancement Of CBR Value By 8% Or More Can Be Achieved By Modifying Expansive Soil With The Addition Of Lime And Coir Pith In The Sub Grade Of Highways. From The Inference, It Is Known That The Pavement Distress Can Be Kept Under Check With The Inclusion Of Additives Like Crumb Rubber, Natural Rubber, And Polymers. Besides These, The Frequently Used Fiber Reinforcing Materials Of Bituminous Concrete Are Coir, Polypropylene, Polyester, And Glass Fibers. Bio-Enzyme, Tyre Cord Fibers, Asbestos Fibers Are Also Used As Additives In The Stabilization Of Expansive Soils. After All The Possible Scrutiny, We Can Conclude That There Is More Exposure In The Area Of Research Concerning The Better Performance Of Pavements With The Usage Of Waste Materials In Terms Of Increasing The Lifespan And Reducing The Pavement Distress Problems Thereby Making The Pavements Sustainable And More Economical.

ABSTRACT

Self-compacting concrete (SCC) referred to as a type of special concrete” offers economical and technical advantages over the normal concrete. So far, the design and development of SCC mixes were carried out as per established design methods. For the first time Bureau of Indian Standards has come out with guidelines for SCC mixes through IS 10262: 2019 revision.

The present study attempts to develop SCC mixes as per the revised IS guidelines utilizing marginal materials such as RMC sludge and granite sludge as fines (particle size less than 125 microns); recycled concrete aggregate as coarse and fine aggregates and GGBS as a filler material. The powder content, cement content and water content were maintained at 550 kg/m³, 334 kg/m³ and 200 lt/m³, respectively. The developed SCC mixes satisfy the requirements of hardened&fresh properties. The morphology of the microstructure of developed SCC mixes were also analyzed through Scanning Electron Microscopy (SEM).

Results indicate the RMC sludge and granite sludge may be utilized in developing SCC mixes. SCC mixes with granite sludge has shown better performance as compared to SCC mixes with RMC sludge as fines.

Keywords: C&D waste; Granite Sludge; IS: 10262-2019; RMC sludge; Self-compacting concrete.

INTRODUCTION

Self-Compacting Concrete (SCC) was first developed in Japan” [1]. It has become a well-accepted innovation in concrete industry, and is widely adopted, especially for important structures where strength, serviceability and speed of construction are of prime importance. SCC has advantages over normal concrete (NC). It provides better surface finishes, thinner concrete sections, enable easier placement of concrete, faster construction, eliminate the vibration, improved durability, and reduction in site manpower and so on [2,3,4]. In pre-cast industry, where the speed of placing concrete and removal of the elements from the forms at the earliest is essential while also ensuring the surfaces are free from defects [5,6]. **Fig. 1** shows a general comparison between mix proportions of SCC and NC [5,6].

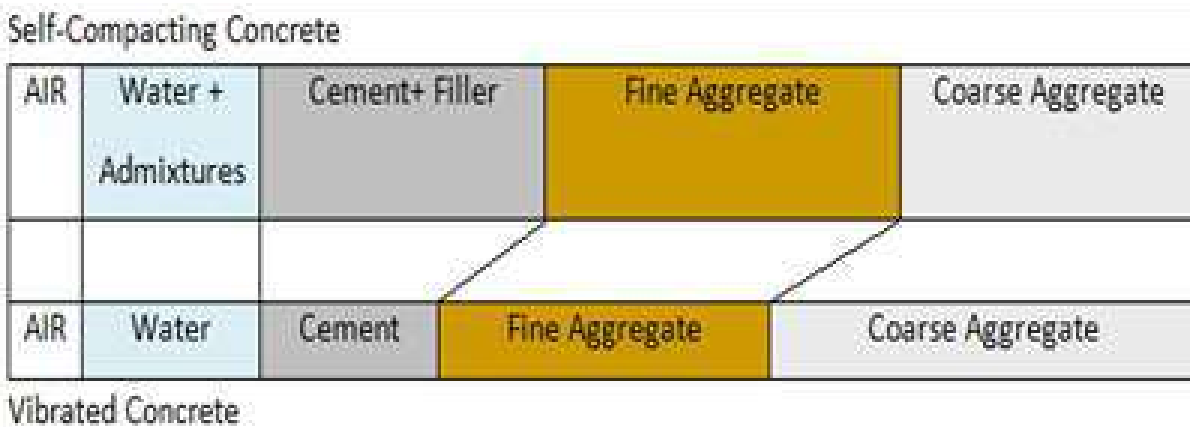

Fig. 1. Comparison of mix proportioning between SCC and NC [1]

SCC has the following property (fresh) requirements viz: filling ability, passing ability & segregation resistance (Fig.2).

<p>Flowing Ability: <i>"The ability to flow into and fill completely all spaces within the formwork, under its own weight". This property is a combination of total flow capacity and flow rate</i></p>	
<p>Passing Ability: <i>"The ability of SCC to flow through tight openings such as spaces between steel reinforcing bars without segregation or blocking"</i></p>	
<p>Segregation resistance: <i>"The ability of SCC to remain homogenous in composition during transport and placing"</i></p>	

Fig. 2. Fresh property requirements of SCC [1]

The requirements for workability of SCC are mainly depend on the applications. Before producing SCC mixes, it is important to understand and measure the fresh properties of SCC. The interpretation of test results with respect to the field applications is also important. SCC is one of the complex types of concrete mix to design. The mix-proportioning process of SCC is more complex as compared to that of NC because the constituents of SCC include rounded or crushed aggregates, ordinary Portland cement or blended cements; different types of mineral admixtures; superplasticizer (SP) and sometimes even Viscosity Modifying Admixture (VMA).

There are number of mix design methods were developed and/or adopted by many researchers, which are based on different principles [7]. While SCC has passed the stage of laboratory practice to field implementation, there are no systematic standards or requirements to be followed in its mix proportioning [7]. Effective proportioning and control of SCC mixes necessitate an authoritative guideline relating the effect of constituent characteristics and corresponding mix proportions.

In India during early 1990's, the public knowledge about the SCC was limited and there are always doubts about the performance. Gradually researchers worked on developing self-compacting concrete, including specifications on fresh and hardened properties. Currently, there are hundreds of technical articles and on SCC has moved from laboratory research to field application. However, the Bureau of Indian Standards (BIS) committee has revised the guideline IS: 10262-2019 [8] which includes SCC mix design method.

RESEARCH SIGNIFICANCE

The construction activities generate large amount of construction and demolition (C&D) waste materials through aggregates, excavated soil, masonry and mortar debris, RMC sludge, marble powder, granite sludge etc. These debris, especially the finer materials are disposed of unscientifically through landfills, lakebeds etc., affecting the environment. It is estimated, in India alone the construction industry generates up to 716 million tons of C&D waste and as per 2016 estimates the city of Bengaluru alone generates about 3600 T/day [9]. Significant attempts have been made to utilize masonry debris, concrete debris and other marginal materials in different construction materials [10,11,12]. Granite sludge (GS) and RMC sludge (RS) (Fig. 3) which are obtained from granite polishing industry and ready-mix concrete plants respectively can be part of C&D waste. Unscientific disposal of these in landfills impacts health, environment, and ecology [13,14]. The best was of disposal of such materials is to utilize them as construction materials, especially in concrete, which is the most widely consumed construction material currently.

Developing SCC mixes using alternatives to natural resources is important in environmental protection and achieving sustainability in construction. Developing SCC mixes using alternatives or other marginal materials is certainly most challenging as compared to developing the other types of concretes. This is due to the complexities involved in achieving equilibrium amongst different constituent materials used in proportioning SCC mixes.

In the revised guidelines IS 10262: 2019 [8] the fines of about 8% (in fine aggregate) is recommended in proportioning SCC mixes and these fines content (8%) is pivotal in determining the fine aggregate content. It is impractical for specific percentage of fines either to be present in fine aggregate; (or) procure fine aggregate with specified value of fines (particle size < 125 μ); nor

assume fine aggregate to have specific fines content irrespective of its gradation characteristics and zonal classification. Even fine aggregates belonging to any particular zone as per IS 383: 2016 [15] shall consists of fines content (%) in a broad range of values and not a specific value. Also, there are no specific recommendations regarding the possible measure which one has to adopt under such circumstances i.e., when percentage of fines is more than or less than a specific value. This is evident in current case, especially when the percentage of fines in procured fine aggregate is less than specific value ($< 8\%$). To attain the required fines content in fine aggregate, it may be necessary to add fines in addition to existing fines content in fine aggregate, thereof to calculate fine aggregate content and estimate the coarse aggregate content for given SCC mix.

The present study attempts to develop SCC mixes using IS 10262: 2019 [8] along with different fine materials (particle size $< 125 \mu$) and filler material. The study primarily focuses on developing the SCC mixes as per IS guidelines and exploring the possibilities of utilizing marginal materials as fines.

EXPERIMENTAL METHODOLOGY

Materials

The list of constituent materials and their corresponding properties are tabulated in **Table 1**.

Table 1. Properties of material

Sl. No.	Materials	Specific gravity	Specific Surface (m ² /kg)	Water absorption (%)
1	Cement – “(OPC-53 grade) conforming IS:12269-2013”[16]	3.14	280	-
2	Fine aggregate – (RFA) “confirming” to Zone-II as per IS 383-2016” [15]	2.58	-	6.00
3	Coarse aggregates –(RCA) 20mm maximum size of aggregate	2.78	-	5.83
4	“Ground Granulated Blast Furnace Slag (GGBS) - IS 12089-2018”[17]	2.85	425	-
5	Superplasticizer (SP) - Polycarboxylic Ether (PCE) based conforming to IS: 9103-1999 [18]	1.09	-	-
6	RMC Sludge (RS)	2.14	435	-
7	Granite Sludge (GS)	3.65	365	-
8	Water - Conforming to IS 456 - 2000 [19]	1.00	-	-

Mix Design Method

The “SCC mixes were developed” based on IS code recommendations. The details are presented through the flow chart (**Fig. 4**) and brief discussion below.

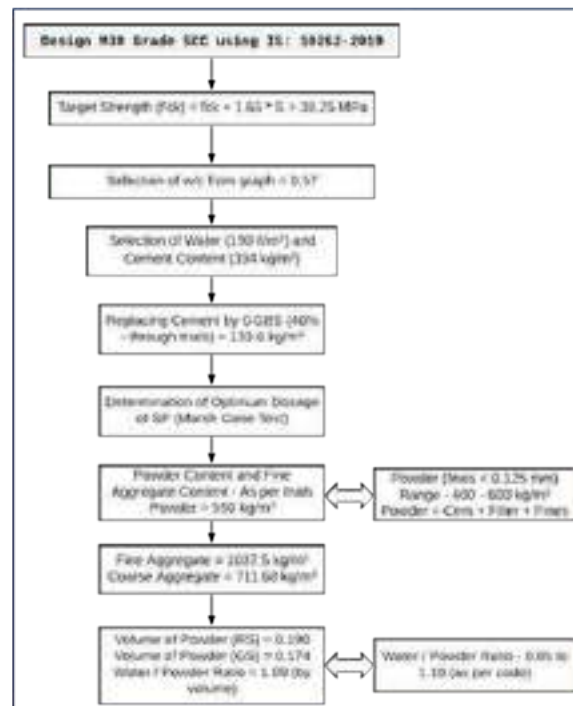

Fig. 4. Flow chart representing the mix design adopted (M30 grade SCC)

The target strength was calculated based on the equation recommended. The selection of water content was based on the graph of water content v/s compressive strength (which dependson the grade of cement) as suggested in IS code. The recommended water content range was 150 - 210 lt/m³. About 190 lt/m³ was chosen based on trials and practical field application. The cement content was calculated on basis of water content chosen and the percentage replacement of filler by weight. After trials, about 40% GGBS by weight of cement was added as filler since replacing 25-50% by weight of cement by filler not yielded required flow for SCC trials. Marsh cone test was performed to decide on optimum dosage of SP.

The recommended powder content range as per IS 10262 2019 [8] is 400 to 600 kg/m³. The powder content constitutes of cement, filler, and the fines (content) in the fine aggregate. It is required to determine the powder content to decide on mixes. Though exact procedure is not stated, the powder content was established through trials in the present study and the values were verified against the ratio of w/p by volume recommended (0.85 to 1.10) under a note in section E-7.5 of IS code. This value of powder content is important since the fine aggregate content can be established only using the fines content of the fine aggregate. The relation is given by:

Total powder content = cement + filler + 10% fines of zone II fine aggregate.

Fine = Powder – (cement + filler)

The fines present in fine aggregate was considered to be 8%, to calculate the fine aggregate proportion. The mass of coarse aggregate for the mix is then determined from the volume of coarse aggregate. The “volume of coarse aggregate” is determined by deducting the volume of air content, water, cement, filler, admixture, and fine aggregate from per meter cube of concrete. The w/p ratio determined must lie between 0.85 and 1.10.

Trials Mixes

To begin with, the trials were conducted with lower powder content. The fine aggregate confirms to zone–II, however it consisted of 1.40% fines. The remaining, fines content to achieve 8% fines was externally added by utilizing various marginal materials having particle size <0.125 mm. Natural river sand fines (NF), marble powder (MP), fly-ash fines (FF), RMC sludge (RS) and granite powder (GS) were utilized as the substitute for fine aggregate fines. The IS code recommends the powder content in the range of 400 to 600 kg/m³. More than 30 trials are reported, which the powder content in the recommended range. Details of trials are tabulated in **Table 2**.

Table 2. Detail of trial mixes

Mix No	Cement	GGBS	Fine aggregate (FA)	Coarse aggregate (CA)	Fines	Powder	Water	SP (%)	w/p	Slump flow (mm)	Result

Fig.5. Final reference mixes

The results indicate the SCC mixes were not achieved at lower powder content (about 400 kg/m^3) these mixes also exhibit lower cement content ($< 250 \text{ kg/m}^3$). SCC mixes showed segregation and bleeding, when the powder content was in range of 400 to 520 kg/m^3 . It is also interesting to note, the w/p ratio was achieved in some of the mixes and the value was near to the upper limit of 1.10 in the mix (mix no.19) which achieved maximum flow of 500mm. The upper limit of 1.10 also finds its mention in literatures of EFNARC [20]. The SCC mixes were only achieved when powder content was above 550 kg/m^3 . IS code recommending the value of powder content between 400 – 600 kg/m^3 ; though EFNARC [20] allows up to 650 kg/m^3 . Thus, 550 kg/m^3 (powder) was considered for further study.

The control mixes were developed based on these criteria. Further, the 8% fines content was achieved with four different types of materials viz., natural fines (CM-M1). For remaining mixes, NF was replaced by RCA fines, RS fines and GS fines for same mix proportions (CM-M1). The adopted mixes in current study (**Fig. 5**) are tabulated through **Table 3**.

Test Details

Fresh properties of SCC mixes studied were established through slump flow test by recording flow diameter in mm; difference in height between outer and inner sides of J-Ring apparatus was recorded in mm and time for flow through V funnel was

recorded in seconds. These tests values were ascertained as per EFNARC guidelines as recommended in IS code [8]. As far as mixing sequence is concerned, a modified procedure where water along with SP followed by cement, filler, FA and CA was adopted [21,22]. For each of SCC mixes, specimens were subjected to compression, split tensile and flexural strength tests at 28 days ageing and were determined as per IS 516 [23].

RESULTS AND DISCUSSIONS

Fresh Properties

Fresh properties of SCC ascertained, are tabulated through Table IV. Slump flow was recorded to check the mobility of SCC. Passing ability to verify ability of the mixes to get through narrow or congested areas of rebars. The stability and homogeneity of SCC was evaluated via resistance to segregation.

Table 4. Fresh properties

Mix Designation	Slump flow (mm)	T50cm (sec)	J-ring (mm)	V-funnel (sec)	
				V0	V5
M1	615	3.0	6.0	7.2	10.8
M2	615	4.6	5.5	8.6	11.4
M3	620	5.3	10.0	7.1	10.7
M4	605	4.3	6.5	7.4	10.5

The developed SCC mixes satisfied the requirements of fresh properties as the values recorded were within the recommended range [20]. The slump flow values recorded range from 605 to 620 mm, T50cm from 3.0 to 5.3 sec, J-ring 5.5 mm to 10 mm and V-funnel at zero minute from 7.1 to 8.6 sec. This shows SCC mix may be developed by using revised IS code with some modification in the mix design procedure and with marginal materials as fines. The viscosity of the mix was ascertained through T50cm and the segregation resistance was assessed through V-funnel.

Hardened properties

Strength properties of SCC viz., compressive strength, flexure and split tensile strengths were tested for 28-day ageing and are tabulated in Table 5 against their corresponding SCC mixes. Fig. 7 shows the Scanning Electron Microscope photograph (SEM) of SCC mixes. A similar microstructure was reported by Sequeria et. al [24] while exploring mud concrete mixes by utilizing other forms of C&D waste.

Table 5. Hardened properties

Mix Designation	Compressive Strength (MPa)	Split Tensile Strength (MPa)	Flexural Strength (MPa)
M1	36.2	3.5	6.8
M2	30.0	2.3	6.6
M3	25.0	2.7	5.0
M4	31.3	2.5	3.8

The increase in strength linearly to increased powder content (for all water contents) may be attributed to higher paste content coating aggregates through continuous matrix of hydrated cement paste. A well-defined cement paste matrix may have also resulted in better packing. In certain instances, but not all, an apparent optimality of powder with respect to compressive strength was noted, though the number of mixes is limited. CM in comparison, with the SCC mix consisting of granite dust as fines has given the satisfactory result.

The water demand for mix M3, consisting of RS fines has increased by about 10% as compared to other proportions with slight increase in SP dosage to achieve similar slump flow values. an increased w/p ratio, which may reflect increased specific surface as compared to other mixes. Understandably, the highest strength characteristics were observed in proportions containing natural aggregates and natural fines (M1-CM); least strength characteristics were observed in mixes M3 & M4, having RS and GS as fines. However, mix proportions different constituents for each series (M1 to M4) are quite similar, in addition to fresh characteristics.

Natural + CM – M1 – CM

CONCLUDING REMARKS

IS 10262:2019 guidelines may be considered for utilizing fines ($<125\mu$) in SCC mixes. The study also reveals that powder plays a major role in achieving SCC mix. The 8% fines in powder content plays a major role in constituting fine aggregate content. The fines ($< 125\mu$) in fine aggregate may vary from 0 - 10% (Zone II – IS 383-2016); if the fines present is less than (or even greater than) 8%, the type of material which should be added to fulfill 8% fines is not suggested in the guidelines. When the powder content was less than 550 kg/m³ the desired SCC mixes were not achieved. The SCC with RS fines demands more water content; the mix was sticky (cohesive) as compared to mixes with GS fines. However, mix containing GS fines exhibited better results in fresh and hardened state.

ACKNOWLEDGMENT

The authors would wish to acknowledge KSCST, Bengaluru for their monetary support for this research work and RASTA – Center for Technology, Bengaluru for their support for conducting experiments. Mr. Karthik and Mr. Zeeshan Ahmed, former M.Tech Students, CIM, RASTA – Center for Road Technology in conducting experiments.

Analytical Estimation of Boundary Layer Thickness for Flow Over Spillways

Suresh Kumar N, Prasanna S V S N D L

Department of Civil Engineering, College of Engineering (A), Osmania University, Hyderabad

✉ nskdr@yahoo.co.in

ABSTRACT

The Spillways provide a safe passage for the excess water or flood water in the reservoir. The present study was emphasized towards estimation of boundary layer thickness, wall shear stress, and skin friction coefficient for flow over spillways. These parameters are helpful in estimating the flow resistance over the spillway and can be made use of in the design of energy dissipators. Analytical estimates were made for the above parameters making use of equations available in the literature. The boundary layer thickness was evaluated for four different discharges.

Keywords: Boundary layer thickness; Velocity; Depth of flow.

INTRODUCTION

A boundary layer is a very thin layer close to the surface where viscous forces and rotationality are considered. The boundary layer will form on the spillway flow, beginning from the crest of the spillway. The thickness of the boundary layer (δ), will grow with the distance from the profile of the spillway crest. The region of transition from laminar to turbulent boundary layer develops far upstream. An increase in the surface roughness will result in faster boundary layer growth. Hence, it will result in reduction of zone of flow development length. The boundary layer thickness will become equal to the depth of flow over the spillway at some point, provided the required length of spillway is available. The flow over the spillway crest is similar to the flow over a streamlined object. As the flow over the spillway will be accelerating, the flow may have a favourable pressure gradient. Hence, the chances of flow separation are not likely to occur till the head over the crest is substantially large (greater than three times the design head) [1].

Review of Literature

For the computation of turbulent boundary layer, Chow adopted a practical method as detailed in the “equation (1),” for the boundary layer growth over the profile of the spillway. This procedure is applicable to channels with mild slope wherein flow is either uniform or accelerating, or channels having steep slopes. The region of transition from laminar to turbulent boundary layer develops far upstream from the zone of consideration. An increase in the surface roughness will result in faster boundary layer growth. Hence, it will result in reduction of zone of flow development length [2].

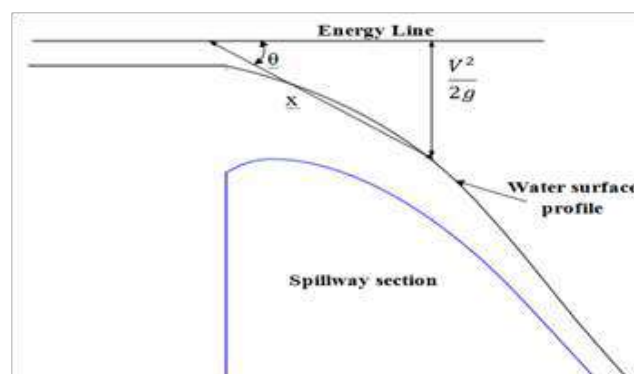

Fig. 1. Boundary Layer Growth

$$\left. \begin{aligned} \frac{\delta}{x} &= \frac{0.024}{\left(\frac{x}{k}\right)^{0.13}} \\ \frac{V^2}{2g} &= x \cdot \sin \theta \end{aligned} \right\} \quad (1)$$

Case Study

The present investigations were carried out for Nagarjuna Sagar project. It is built at 2.4 km downstream of Nandikonda village of Miryalaguda Mandal of Nalgonda District in Telangana State. It is located at 79°18' 47" E longitude and 16°34'23" N latitude. The project comprises of 124.66 m (409 ft) high masonry dam with total volume of 199 million cu ft. The salient features of the case study are highlighted in **Table 1** [3].

Table 1. Salient feature of NS dam

Description of Parameters	Details
Maximum Water Level (MWL)	181.100 m
Full Reservoir Level (FRL)	179.832m
Discharge (Q)	58,340m ³ /s
Top of the Dam (TOD)	184.40 m
Crest level of Spillway	166.421 m
Height of the spillway	166.421 – 67.06 = 99.361m
Maximum height of the dam	124.66 m
Length of spillway	470.916 m
Pier thickness	4.572m
Average River Bed Level	184.40 – 124.66 = 59.74 m
Size of each bay of crest gates	13.716 x 13.41m
Constants	Kp = 0.01 and Ka = 0.1

METHODOLOGY

The present investigation adopts standard ogee shaped spillway profiles developed by U.S. Army Corps of Engineers at Waterways Experiment Station (WES). The study adopts “equation (2),” for the spillway crest upstream profile with origin at the crest of the spillway and uses “equation (3),” for downstream spillway profile [4]. The curve extends 0.270H_d (X_c) on upstream and 0.125H_d (Y_c) below the crest point of the spillway as shown in the **Fig. 2**.

$$Y = \frac{0.724(X + 0.27H'_d)^{1.85}}{H'_d} + 0.126H'_d - 0.4315H'_d{}^{0.375} (X + 0.27H'_d)^{0.625} \quad (2)$$

$$X^n = K.H'_d{}^{n-1}.Y \quad (3)$$

The analytical values of boundary layer thickness (δ) for hydraulically smooth surface were estimated by the “equation (4) to (7),” [5]. The boundary layer thickness values were evaluated for four different discharges viz., 58,340 cumec, 43,755 cumec, 29,170 cumec and 14,585 cumec.

$$\frac{1}{\sqrt{C_f}} = 3.85 * \log\left(\frac{\delta U}{\nu}\right) + 3.67 \quad (4)$$

$$C_f = \frac{b_s}{(\log R_x)^{2.38}} \quad (5)$$

$$b_s = 0.32 + 8.15 * k_s^{0.47} \tag{6}$$

$$\tau_w = \frac{0.0315 * \mu^{1/7} * \rho^{6/7} * U^{13/7}}{x^{1/7}} \tag{7}$$

where

X, Y = coordinates of the upstream and downstream profile (m)

n, K = variable parameters which depend on the inclination of the upstream face of the dam, n = 1.85 and K = 2.0

H_d = Design head (m)

V is the velocity at 'x', m/s

θ is the angle w.r.t the total energy line above the crest of the spillway, degrees

δ is the boundary layer thickness, m

C_f is local loss coefficient

b_s empirical coefficient accounting for sand grain roughness

x is the point of interest on the WES profile of spillway, m

k_s is the surface roughness height, m

τ_w is the wall shear stress, Pa

μ is the dynamic viscosity, Ns/m²

ρ is the mass density of water, kg/m³

U is the stream velocity at the point of interest, m/s

The point, at which boundary layer thickness coincides with the free surface, is the location at which flow is fully developed. The plots for the point of intersection of boundary layer thickness and depth of flow for various flow conditions are shown in Fig. 3 (a) to (d).

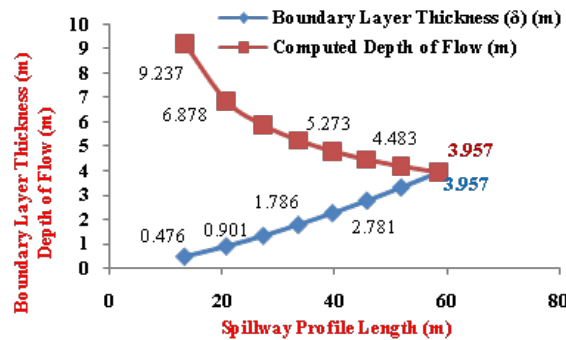

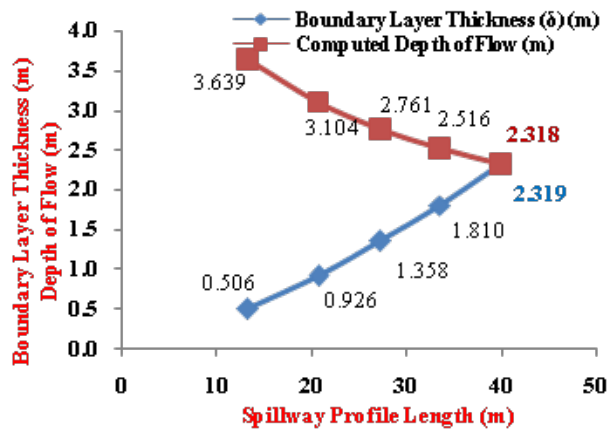

Fig. 2. WES Profile of Spillway

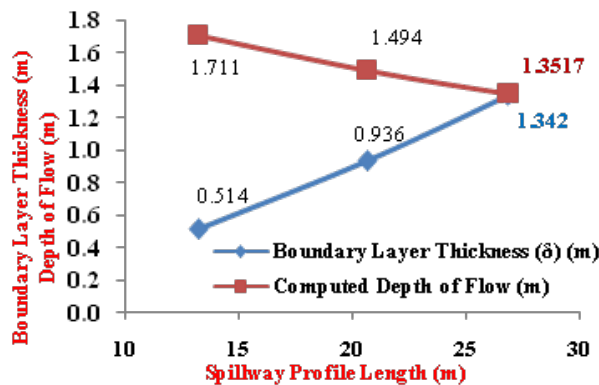

(a) Plot of 58,340 cumec

(b) Plot of 43,755cumec

(c) Plot of 29,170cumec

(d) Plot of 14,585cumec

Fig. 3. Intersection point of Boundary Layer and Depth of flow

It can be seen from the Table 2 that the distance of flow development is decreasing with the reduction in the design discharge over the spillway. Moreover, it is also observed that, even the thickness of boundary layer is decreasing for the reduced flow rates. This is due to the fact that, as the lead distance from the crest of the spillway is decreasing, the Reynolds number is decreasing. As a consequence of this, the thickness of boundary layer is decreasing.

Table 2. Boundary layer thickness values

Discharge	Spillway Profile Distance	Velocity	Reynolds Number (R_x)	Boundary layer thickness (δ)	Depth of flow on the profile of spillway (y)
cumec	m	m/s	$\times 10^8$	m	m
58,340	58.755	31.144	18.38	3.978	3.978
43,755	49.926	29.301	14.57	3.172	3.171
29,170	39.888	26.710	10.62	2.319	2.318
14,585	26.848	22.913	6.13	1.342	1.352

The analytical estimations of wall shear stress were evaluated from the “equation (7)”. The values of computed wall shear stress are detailed in **Table 3**. The graph detailing the variation of wall shear stress from the crest of the spillway to the lip level of the bucket is shown in **Fig. 4**. Velocity reduction away from the boundary layer will be dependent on the magnitude of shear stress and is independent of how it arises.

The skin friction coefficient (C_f) is a component of profile drag, which is a resistant force exerted (on the spillway) and is useful in estimating total frictional drag exerted (on the spillway). The flow resistance over the spillway can be made use of in the design an energy dissipator, at the downstream end of the spillway.

Table 3. Computed wall shear stress values

Spillway Profile Distance (m)	Velocity (m/s)	Reynolds Number ($\times 10^8$)	Computed Wall shear stress (Pa)
13.232	13.412	1.77	375.8154
20.646	18.012	3.70	705.9213
27.231	21.019	5.70	956.4057
33.433	23.494	7.82	1186.1176
39.534	25.671	10.10	1401.6097
45.636	27.638	12.6	1607.586
51.737	29.450	15.2	1808.8093
57.838	31.144	18.2	2006.7861
67.154	34.743	23.2	2314.3997
114.584	43.753	49.9	2814.7607
148.661	44.345	65.7	3025.4808

Fig. 4. Analytical variation of wall shear stress

RESULTS AND DISCUSSIONS

The present study was carried out for Nagarjuna Sagar project.

- Analytical estimates were carried out to evaluate the intersection point of boundary layer thickness and depth of flow over the profile of the spillway.
- It is proved from the calculations that the thickness of boundary layer is decreasing with the reduction in the design discharge as well as with the lead distance from the crest of the spillway.
- The results of wall shear stress and skin friction coefficient are useful for the estimation of flow resistance that can be adopted in the design energy dissipators.

Department of Soil & Water Conservation Engineering, College of Technology, GBPUA&T Pantnagar, Pantnagar, Uttarakhand

*✉ deepak.swce.cot.gbpuat@gmail.com

ABSTRACT

Flood is generally a natural disaster which has a everlasting consequences in terms of loss of life and property. It is world's most pervasive hydrological threat that affects the conservation of resources, wildlife, economic activities etc. In this paper, flood mapping has been done for a very flood prone region of Bihar. Bhagalpur, which is situated on the southern bank of river Ganga. Sentinel-1 SAR (Synthetic Aperture Radar) images has been used for mapping the study area. The Sentinel-1 SAR imagery has been use for the month of September-October 2019. Sentinel-1 satellite operating in C-band is the major breakthrough in the development of SAR application. Vertical-Horizontal (VH) polarization configuration and Lee filtering 7×7 window sizes has been used and image processing has been done using SNAP. Two methods were applied to flood maps from Sentinel-1 SAR images: RGB (Red, Green, Blue colour model) composition based on the differences between the pre- and post-event images; and the calibration threshold technique or binarization based on histogram backscatter values. The result suggested that out of 2100 km² region selected for study, 907 km² areas was severely affected by flood.

Keywords: Sentinel-1; Flood mapping; SAR imagery; VH polarization; Bihar.

INTRODUCTION

With rapid urbanization, global warming, and growing demand on present services, infrastructures are now falling into the hazard-prone areas. Bihar susceptibility to floods can be understandable from the ongoing situation that floods in Bihar become an annual feature. Some or the other districts face flooding situations almost every year. Bhagalpur district is under severely affected flood prone district in Bihar which face flood every year. In present study, Sentinel-1 imagery is used to develop flood map of study area. Several researches has been done on using sentinel-1 imagery for flood study (Twele et al. 2016; Clement et al. 2018; Li et al. 2018; Uddin et al. 2019; Liang and Liu 2020). Bazi et al. (2005) used SAR images obtained from ERS-2 satellite to detect the flooded areas in the City of Pavia and City of Bern during the flood event of October 2000. Further, Borah et al. (2018) analysed the use of Sentinel-1 SAR images for flood inundation monitoring and mapping of the Kaziranga National Park (KNP) during the monsoon period in 2017. Dual polarized (VH, VV) SAR images were used to generate inundation map. The investigation observed that out of the total area within KNP, an area of 23,487.8 ha (61%) was under land features, 2270.31 ha (6%) under permanent water bodies and 12,660.28 ha (33%) was under monsoon flood. Hakdaoui, S. et al (2019) presented a technique to supervise wetland areas after the flash flood event in Laayoune city (Southern Morocco) situated in the arid region of Sahara Desert. The proposed method uses multi-sensor images i.e. SAR images and optical images to find the inundated land. The overall accuracy of the land cover map and flood inundation mapping was found to be 87.51% and 96.44% respectively. The total flooded area for April, June and August 2017 corresponded to 2.01%, 4.53% and 7.01% respectively. Similarly, Nasirzadehdizaji, R., et al (2019) mapped the flood event in Lake Urmia, Golestan Province and Khuzestan province of Iran during 2019. The GRDH Sentinel 1 C-Band SAR images with VH and VV polarization in Interferometric Wide (IW) swath mode were used for flood mapping. In the present study, the flood mapping.

STUDY AREA DESCRIPTION

Bhagalpur is the district in Bihar known as silk city of India (Kingsley 1897; Tannen 1986). The Bhagalpur district has population more than 30 lakhs with density closer to 1200 people per square kilometers (Minister of Home Affairs 2011).

Fig. 1. Sentinel 1 imagery for Bhagalpur region

The river Ganga has been the lifeline of Bhagalpur (Bihar) (Agrawal 1994; Singh et al. 2003). The present study area is situated between 25.1070 – 25.4560 N latitude and 86.5720 – 87.2210 E longitude.

The study area is shown in **Fig. 1**. The Sentinel image has been taken for 2019. The processing of Sentinel 1 imagery has been done using SNAP (Sentinel Application Platform).

TOOLS USED FOR IMAGE PROCESSING

The processing of Sentinel 1 imagery has been done using SNAP (Sentinel Application Platform).

SNAP is a set of executable software and application programming interfaces (APIs) designed to enable the use, display and, analysis of a range of remotely sensed data. In this study, Sentinel-1 SAR images has been used because of their features, configuration, and the free data set available online from Earth Observation (EO) data resources. The Sentinel-1 sensor is part of an ESA (European Space Agency) satellite constellation. It is composed of Sentinel-1A, launched on 3 April 2014, and Sentinel-1B, on 22 April 2016. Both satellites have a useful life of 7 years and a 12-day orbital repetition cycle (6 days between them). These temporal limitations of image capture mean that we did not have images of the day of the highest level of the Ebro at the study points. The available image that was closest to the moment of maximum flood was from 13 April 2018 and it was the one used for the development of the study. Each image has a coverage range of 250 km with a 5×20 m resolution. The images are Level-1 Ground Range Detected (GRD) products; this means that they were detected, multi-looked, and projected to the ground range using an Earth ellipsoid model. The acquisition mode is Interferometric Wide Swath, and the images have a high resolution; the sensor pass is ascending, with incidence angles between 29° and 46° , and dual polarization, VV (Vertical-Vertical) and VH (Vertical-Horizontal). The study area is covered by VV and VH only according to the observation scenarios shown in Earth Observation Data Center for Water Resources Monitoring (EODC).

The pre-processing of sentinel 1 GRDH SAR images was performed in SNAP software using the Sentinel 1 toolbox. The flow chart for the same has been shown in Fig. 2. The post processing steps are done in QGIS software. Final flood mapping for this study area were obtained using VH polarization configuration and Lee filtering 7×7 window sizes. Two methods were applied to flood maps from Sentinel-1 SAR images: RGB (Red, Green, Blue colour model) composition based on the differences between the pre- and post-event images; and the calibration threshold technique or binarization based on histogram backscatter values.
